Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of the joint technical committee is to prepare International Standards. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 29157 was prepared by Joint Technical Committee ISO/IEC JTC 1, *Information technology*, Subcommittee SC 6, *Telecommunications and information exchange between systems*.

Information technology — Telecommunications and information exchange between systems — PHY/MAC specifications for short-range wireless low-rate applications in the ISM band

1 Scope

This International Standard specifies the PHY characteristics and MAC procedures used for short-range, low-data-rate, wireless communications with very low latency and point-to-multipoint connection capability.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

None.

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1

pico-net

small operational range for wireless transmissions within about 10 meters in radius from the user or his/her device

3.2

group

total of devices interoperable within a pico-net, with their usage of the same group code separating them from other devices in different groups

3.3

master

device transmitting the reference synchronisation signal within a group

3.4

slave

device that is not a master

3.5

scan

process performed by slaves to search for the synchronising signal from the master

3.6

middleframe

basic unit of frame operation, consisting of one control frame and one or more payload frames

NOTE Sixteen middleframes constitute a superframe.

3.7

superframe

bigger frame consisting of sixteen middleframes

NOTE The superframe is the overall operational unit of pico-net MAC operations.

3.8

scan code

7-bit seed to generate one of the 127 gold codes which has a value between 1 and 127

3.9

open code

code used for broadcasting

3.10

closed code

code used exclusively for a specific communication group or purpose

3.11

group code

code to discriminate among communication groups

NOTE Either an open or a closed code may be applied.

3.12

security code

code applied to message data to enhance security or privacy of the communication

NOTE Either an open or a closed code may be applied.

4 Abbreviated terms

BF	beacon frame
DME	device management entity
FBF	fast beacon frame
FSK	frequency shift keying
GFSK	Gaussian frequency shift keying
ISM	industrial, scientific, and medical
MAC	medium access control
MACF	MCF acknowledge control frame
MCF	master control frame
MLME	MAC sublayer management entity
MLME-SAP	MAC sublayer management entity-service access point
MPDU	MAC protocol data unit
MSDU	MAC service data unit
PD-SAP	PHY data service access point

PDU	protocol data unit
PF	payload frame
PHY	physical layer
PLME	physical layer management entity
PLME-SAP	physical layer management entity - service access point
PPDU	physical layer protocol data unit
PSDU	physical layer service data unit
RACF	RCF acknowledge control frame
RCF	request control frame
RF	radio frequency
RSSI	received signal strength indication
SAP	service access point
SDU	service data unit

5 Overview

There may be many applications in the ISM band. Such applications that require a short-range wireless communication channel can be listed as follows in the order of data rates; video, audio, voice, control, sensor, and so on. A different platform for a different application may be an ineffective way in light of cost, time-to-market, compatibility, etc. It would be beneficial to have a single platform which is capable of accommodating all these applications with the least overhead.

This International Standard is intended to provide a unified yet efficient and versatile platform for low-power, low-data-rate, short-range wireless communication applications. It is possible to accommodate diverse services of different nature in a single platform.

For mobile applications, low power consumption is one of the most important factors. To save power, data rate should be traded-off. This International Standard aims for the applications of 1 Mbps or less. To minimise implementation effort, it assumes the use of off-the-shelf RF components for the ISM band.

The International Standard makes use of frequency hopping, time-division multiple access, and time/frequency hybrid diversity. Frequency hopping is adopted to render immunity to the channel variations and to provide independent simultaneous communication channels. Time-division multiple access provides one with the control of interference of strong adjacent signals which otherwise should be avoided using an elaborate manipulation. The diversity technology is the means to maintain quality-of-service in the ISM band where channel fading is of serious concern.

Each device in the pico-net formed by this International Standard is either a master or a slave. In the pico-net, there exists only one single master which transmits a beacon signal to which all the other devices (slaves) are synchronised. The beacon signal contains the time synchronisation information and the frequency hopping pattern table. The frequency hopping pattern table contains the 16 best frequencies which are selected by sounding algorithms (see 7.4.5).

Figure 1 — A group communication example

At start-up, the master checks the frequency channels and selects the best 16 channels out of 80 to form a table of sixteen orthogonal frequency hopping patterns (see 8.4.2). Each frequency hopping pattern corresponds to a channel. The master assigns a communication channel (or channels) using the MCF (Master Control Frame) to be described below (see 7.4). Within each communication channel which is specified by a unique frequency-hopping pattern, the devices communicate with each other using time-division multiple access without any other intervention of the master.

The pico-net may have up to sixteen independent simultaneous communication channels. Within each communication channel, point-to-multipoint communication (broadcasting) is possible not to mention one-to-one communications. Moreover, each device may switch to another communication channel other than the current one if permitted by the master. Figure 1 shows an example of group communication in the pico-net. The master (M) transmits a beacon signal and is communicating with only one slave (S). The other slaves are communicating with another via other channels independently of the master.

Data are encased into the well-tailored standard units of a frame, a middleframe, and a superframe (see 8.3). Figure 2 shows the relationship between these units. These data formats are synchronised to the master beacon signal. To accommodate different applications in a single framework, this International Standard fixes the length of protocol frames to 16 ms which gives a permissible level of latency in most applications. A middleframe consists of frames. Sixteen middleframes constitute a superframe.

A frame is categorised into one of the seven kinds depending on its use: (1) a beacon frame (BF), (2) a fast beacon frame (FBF), (3) a request control frame (RCF), (4) a master control frame (MCF), (5) an RCF acknowledge control frame (RACF), (6) an MCF acknowledge control frame (MACF), and (7) a payload frame (PF). All the frames except the payload frame (PF) are control frames. All the frames have an identical format consisting of Lock Time, Preamble, Header, Message, and EoF Delimiter (see 8.2). Header is used to identify the kind of the frame. The message field is used to convey information and data necessary for communications (see 7.1-7.7).

Figure 2 — Data formats: a frame, a middleframe, and a superframe

A middleframe consists of one control frame and one or more payload frames (PF's). The middleframe starts with a control frame whose length is fixed to 0,88 ms. The length of the middleframe is fixed to 16 ms. The length of the payload frames varies depending on applications. The maximum number of payload frames within a middleframe is eighteen. Carrier frequencies hop in harmony with the middleframes.

A superframe consists of sixteen middleframes and is of 256 ms. Superframes have two modes: a normal mode and a fast synchronisation mode (see 8.3.2). A fast synchronisation mode is used for robust synchronisation. In a fast synchronisation mode, a frame called 'fast beacon frame (FBF)' is used instead of 'beacon frame (BF)'. Two modes may be interchangeably adopted by the unit of a superframe.

For security reasons, the preamble in the frame uses Gold codes for group identification. The message field data are also encrypted with security codes (see 9.3.2).

The MAC/PHY services and primitives will be defined and described in Section 6.

This International Standard uses the 2,4 GHz band and offers two classes of power transmission levels. Class one is up to 100 mW and class two is up to 10 mW. As a modulation scheme, the International Standard uses (G)FSK (see 9).

6 Interlayer service specification

This clause defines the interface between the MAC and PHY layers, and between the MAC layer and the upper layer.

6.1 Overview

Both MAC and PHY layers conceptually have management entities, called the MLME (MAC Layer Management Entity) and the PLME (PHY Layer Management Entity), respectively. These entities provide a service interfaces for the layer management functions.

The PHY provides data and management services through two SAPs (Service Access Points). The PHY data services are provided through the PD-SAP (PHY Data SAP), and PHY management services are provided through the PLME-SAP. The DME-PLME_SAP is equivalent to MLME-PLME-SAP except that it operates through DME rather than MLME.

The MAC provides data and management services through two SAPs (Service Access Points). The MAC data services are provided through the MAC-SAP, and MAC management services are provided through the MLME-SAP.

In order to provide correct MAC operation, each device must possess a DME (Device Management Entity). The DME is a layer-independent entity and act under the direction of a higher-level management application. Figure below depicts the relationships between the various management entities.

Figure 3 — The protocol model used in this International Standard

6.2 General format of management primitives

Each sublayer's specific management information is organised into the relevant Management Information Base (MIB). Corresponding to the MIB of the PAN, the LAN/MAN contains the MIB that operates according to the Simple Network Management Protocol (SNMP). However, since management within network is restricted to an individual network (i.e. one network does not interfere in the management of another) the MIB is used to define the specifications of each sublayer.

MLME and PLME are assumed to have a MIB for each sublayer, and the management primitives of the MIB are exchanged by means of management SAPs. The manager can "GET" or "SET" the value of the MIB attribute via the primitives. The "SET" request primitive can also trigger certain actions within the relevant layer.

A "GET" or "SET" primitive may be expressed in the form of a request accompanying a confirm primitive. Such primitives have the prefix MLME or PLME depending on whether the point of exchange is the MAC SAP or the PHY SAP. DME utilizes the services provided by MLME through the MLME SAP.

In Table 1, "XX" stands for "MLME" or "PLME", and the parameters of the primitives are defined in Table 2.

Table 1 — General management primitive overview

Name	Request	Confirm
XX-GET	6.2.1	6.2.2
XX-SET	6.2.3	6.2.4

Table 2 — MLME/PLME general management primitive parameters

Name	Type	Valid range	Description
MIBattribute	Octet string	Any MIB attribute	MIB attribute name
MIBvalue	Variable		MIB value
ResultCode	Enumeration	SUCCESS, INVALID_MIB_ATTRIBUTE, READ_ONLY_MIB_ATTRIBUTE, WRITE_ONLY_MIB_ATTRIBUTE	Result of MLME or PLME request

6.2.1 MLME-GET.request and PLME-GET.request

This primitive requests information about the relevant MAC MIB or PHY MIB. The semantics of these primitives are as follows.

```
XX-GET.request (
    MIBattribute
)
```

The primitive parameters are defined in Table 2.

6.2.1.1 When generated

DME and MLME (in the case of a PLME-GET.request) create these primitives to retrieve information from the MAC or PHY MIB.

6.2.1.2 Effect of receipt

The relevant management entity fetches the requested MIB attribute from the database and returns the value as the result of XX-GET.confirm.

6.2.2 MLME-GET.confirm and PLME-GET.confirm

This primitive returns the result of an information request to the relevant MAC MIB or PHY MIB. The semantics of these primitives are as follows.

```
XX-GET.confirm (
    Status,
    MIBattribute,
    MIBattributevalue
)
```

The primitive parameters are defined in Table 2.

6.2.2.1 When generated

DME or MLME (in the case of a PLME-GET.confirm) creates these primitives in response to an XX-GET.request.

6.2.2.2 Effect of receipt

If the status is SUCCESS, these primitives return the value of the relevant MIB attribute, otherwise they return the error code in the status field. Valid error status values include INVALID_MIB_ATTRIBUTE and WRITE_ONLY_MIB_ATTRIBUTE.

6.2.3 MLME-SET.request and PLME-SET.request

These primitives attempt to set the value of the relevant MAC MIB or PHY MIB attribute to the specified parameter. The semantics of these primitives is as follows.

```
XX-SET.request (
    MIBattribute,
    MIBattributevalue
)
```

The primitive parameters are defined in Table 2.

6.2.3.1 When generated

These primitives are created when DME or MLME (in the case of PLME-SET.request) tries to set the relevant MAC/PHY MIB attribute.

6.2.3.2 Effect of receipt

The relevant management entity tries to alter the value of the MIB attribute in the database. If the MIB is a reference to certain actions, this is interpreted as a request to execute the action. The management entity that receives this command responds by returning the result through a call to XX-SET.confirm.

6.2.4 MLME-SET.confirm and MLME-SET.confirm

This primitive returns the result of the attempt to set the MAC MIB or PHY MIB attribute. The semantics of this primitive are as follows.

```
XX-SET.confirm (
    Status,
    MIBattribute
)
```

The primitive parameters are defined in Table 2.

6.2.4.1 When generated

DME or MLME (in the case of PLME-SET.confirm) create this primitive in order to respond to the XX-SET.request.

6.2.4.2 Effect of receipt

If the Status is SUCCESS, this means that the MIB attribute was set to the requested value. Otherwise, the Status field shows the error description. If the specified MIB attribute refers to a certain action, the primitive represents the success or failure of the execution of that action. Possible error status values include INVALID_MIB_ATTRIBUTE and READ_ONLY_MIB_ATTRIBUTE.

6.3 MLME-SAP

In this subclause, the services that MLME provides to DME are defined. These definitions are conceptual and do not specify a certain implementation or external interface.

The MLME SAP primitive generally follows the format of an ACTION.confirm in response to an ACTION.request. The ACTION.indication is used to inform DME of events from other stations. DME uses the services provided by MLME through MLME SAP, and those primitives are outlined in Table 3.

Table 3 — MLME primitive summary

Name	Request	Indication	Response	Confirm
MLME-GET	6.3.1			6.3.2
MLME-MASTER-START	6.3.3			6.3.4
MLME-RESET	6.3.5			6.3.6
MLME-SCAN	6.3.7			6.3.8
MLME-SET	6.3.9			6.3.10

Table 4 — MLME-SAP parameters

Name	Type	Valid range	Description
MIBAttribute	Enumeration		Desired physical layer MIB attribute
MIBStatus	Enumeration	SUCCESS, INVALID_ATTRIBUTE, INVALID_VALUE	Result of request for MIB attribute information
MIBAttributeValue	Various	Attribute specific	Desired physical layer MIB attribute value
ResetResult Code	Enumeration	SUCCESS, FAILED	Response to reset request
ScanNumber	integer	0 ~ 65535	Scan duration is ScanNumber * 256 ms
ScanStartFreq	integer	0 ~ 3	Scan start frequency. Scan frequency round as 0 -> 1 -> 2 -> 3 -> 0 (0 : freq 0, 1 : freq 26, 2 : freq 52, 3 : freq 78)
ScanResult Code	integer	SUCCESS, FAILED, INVALID_VALUE	Return Scan result code
MasterStart ResultCode	integer	SUCCESS, FAILED, INVALID_VALUE	Return Master-Start result code

6.3.1 MLME-GET.request

This primitive requests Information about a MAC sublayer MIB attribute.

6.3.1.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-GET.request  (
                    MIBAttribute
                    )
```

Table 4 define the parameter of this primitive.

6.3.1.2 When generated

This occurs by DME to obtain information from the MAC sublayer MIB of MLME..

6.3.1.3 Effect of receipt

The receipt of the MLME-GET.request primitive by the MAC sublayer entity extracts the requested MIB attribute from the database and sends the results through a MLME-GET.confirm primitive.

6.3.2 MLME-GET.confirm

This primitive report result of the requested information from the MAC sublayer MIB.

6.3.2.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-GET.confirm  (
                    MIBstatus,
                    MIBAttribute,
                    MIBAttributeValue
                    )
```

Table 4 define the parameter of this primitive.

6.3.2.2 When generated

MLME generates this as a response to a MLME-GET.request primitive and sends it to DME.

6.3.2.3 Effect of receipt

If the state parameter is SUCCESS the requested MAC sublayer MIB value is sent, otherwise an error is indicated.

6.3.3 MLME-MASTER-START.request

This primitive requests the process of creating a new network.

6.3.3.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-MASTER-START.request  (
                                MIBstatus,
                                MIBAttribute,
                                MIBAttributeValue
                              )
```

Table 4 define the parameter of this primitive.

6.3.3.2 When generated

This primitive is generated by the next higher layer and issued to its MLME to create a new network.

6.3.3.3 Effect of receipt

This primitive initiate the piconet described in 7.1. The MLME subsequently issues an MLME-MASTER-START.confirm that reflects the results of the creation procedure.

6.3.4 MLME-MASTER-START.confirm

This primitive reports the results of a piconet creation.

6.3.4.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-MASTER-START.confirm  (
                                MasterStartResultCode
                              )
```

Table 4 define the parameter of this primitive.

6.3.4.2 When generated

This primitive is generated by the MLME as a result of an MLME-MASTER-START.request.

6.3.4.3 Effect of receipt

MLME reports the result of the creation process of network. A ResultCode of SUCCESS indicates that the station is now the master.

6.3.5 MLME-RESET.request

This primitive requests a reset of the MAC sublayer.

6.3.5.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-RESET.request  (
                      )
```

This primitive has no parameters.

6.3.5.2 When generated

This is generated whenever a MAC sublayer reset is requested.

6.3.5.3 Effect of receipt

The MAC sublayer resets all transceiver state machines to their initial states.

6.3.6 MLME-RESET.confirm

This primitive reports result of reset the MAC sublayer.

6.3.6.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-RESET.confirm    (  
                        ResetResultCode  
                        )
```

Table 4 define the parameter of this primitive.

6.3.6.2 When generated

MLME generates this as the result of a MLME-RESET.request.

6.3.6.3 Effect of receipt

DME or Adaptation layer is notified of the result of the reset.

6.3.7 MLME-SCAN.request

This primitive define how a device can determine the presence or absence of PANs in a communications channel.

All devices shall provide an interface for these scan primitives.

6.3.7.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-SCAN.request(  
                  ScanNumber,  
                  ScanStartFreq  
                  )
```

Table 4 define the parameter of this primitive.

6.3.7.2 When generated

This primitive is generated by the next higher layer and issued to its MLME to initiate a channel scan to search for master device activity within the POS of the device.

6.3.7.3 Effect of receipt

When MLME receives this primitive from DME, it executes a manual SCAN of the channels in the Channel List. When this SCAN is completed, MLME responds to DME with the result of the SCAN through a call to MLME-SCAN.confirm.

6.3.8 MLME-SCAN.confirm

This primitive and its parameters are collected during the SCAN and sent back upon the completion of the SCAN.

6.3.8.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-SCAN.confirm (
    ScanResultCode
)
```

Table 4 define the parameter of this primitive.

6.3.8.2 When generated

This message is sent to DME when MLME completes the requested SCAN or when the parameters of MLME-request are incorrect.

6.3.8.3 Effect of receipt

On receipt of the MLME-SCAN.confirm primitive, The DME is notified of the results of the scan procedure. If the requested scan was successful, the status parameter will be set to SUCCESS. Otherwise, the status parameter indicates the error.

6.3.9 MLME-SET.request

This primitive request to set the MAC sublayer MIB attribute to the specified value.

6.3.9.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-SET.request (
    MIBAttribute,
    MIBAttributeValue
)
```

Table 4 define the parameter of this primitive.

6.3.9.2 When generated

This occurs by DME to set the MAC sublayer MIB attribute to the specified value and sends it to MLME.

6.3.9.3 Effect of receipt

The receipt of the MLME-SET.request primitive by the MAC sublayer entity attempts to store the specified MAC sublayer MIB attribute in the database and reports the result through a MLME-SET.confirm primitive.

6.3.10 MLME-SET.confirm

This primitive reports result of the attempt to set the MAC sublayer MIB attribute to the specified value.

6.3.10.1 Definition of service primitives

The semantics of this primitive are:

```
MLME-SET.confirm  (
                    MIBstatus,
                    MIBAttribute
                    )
```

Table 4 define the parameter of this primitive.

6.3.10.2 When generated

MLME sends this to Adaptation layer as the response to the MLME-SET.request primitive.

6.3.10.3 Effect of receipt

If the state value is SUCCESS it means the MIB attribute was set as requested, otherwise an error is indicated if the MIB attribute was unable to be set for some reason.

6.4 MAC-SAP

The MAC SAP is the logical interface between the MAC and the higher adaptation layer. This logical interface incorporates a set of primitives and their definitions. These primitives and definitions are described conceptually here, but through this the process of the parameters exchanged between the MAC and adaptation layer can be understood. Table 5 lists the primitives supported by the MAC-SAP. These primitives are discussed in the subclauses referenced in the table.

Table 5 — MAC-SAP primitive summary

Name	Request	Confirm	Indication	Response
MAC-DATA	6.4.1	6.4.2	6.4.3	

Table 6 — MAC-SAP parameters

Name	Type	Valid range	Description
SourceID	integer		Target DEVID of MLME request
DestinationID	integer		DEVID initiating the MLME request
Length	Unsigned Short Integer	0-65535	MSDU length
data	variable length Octet	-	Data portion of MSDU
ResultCode	Enumeration	SUCCESS, INVALID_MIB_ATTRIBUTE	Result of MAC request

6.4.1 MAC-DATA.request

This primitive initiates the data transfer from one MAC entity to another MAC entity or entities.

6.4.1.1 Definition of service primitives

The semantics of this primitive are:

```
MAC-DATA.request (
    SourceID,
    DestinationID,
    Length,
    Data
)
```

Table 6 define the parameter of this primitive.

6.4.1.2 When generated

This occurs when the adaptation layer entity requests transmission of a MSDU(i.e. APDU) to the MAC sublayer entity.

6.4.1.3 Effect of receipt

When this primitive is received, the MAC formats the MSDU according to the input parameters and sends it to the PHY-SAP; then the MSDU passes through the wireless media and is sent to the peer MAC entity. When the MAC sublayer entity has completed the sending, it will issue the MAC-DATA.confirm primitive with a status of SUCCESS.

6.4.2 MAC-DATA.confirm

This primitive confirm that the Adaptation layer entity has sent a MSDU (APDU) to another Adaptation layer entity.

6.4.2.1 Definition of service primitives

The semantics of this primitive are:

```
MAC-DATA.confirm (
    SourceID,
    DestinationID,
    ResultCode
)
```

Table 6 define the parameter of this primitive.

6.4.2.2 When generated

The MAC sublayer entity sends this primitive to the Adaptation layer entity as a response to the MAC-DATA.request primitive when the requested MSDU is transmitted.

6.4.2.3 Effect of receipt

On receipt of the MAC-DATA.confirm primitive, the Adaption layer entity is notified of the result of its request to transmit. If the transmission attempt was successful, the status parameter is set to SUCCESS.

6.4.3 MAC-DATA.indication

This primitive indicates to the adaptation layer that a MSDU has been received.

6.4.3.1 Definition of service primitives

The semantics of this primitive are:

```
MAC-DATA.indication (
    SourceID,
    DestinationID,
    Length,
    Data
)
```

Table 6 define the parameter of this primitive.

6.4.3.2 When generated

This occurs when MSDU received by the MAC has been successfully processed.

6.4.3.3 Effect of receipt

The receipt of the MAC-DATA.indication primitive, the adaptation layer is notified of the arrival of an APDU(i.e. MSDU) across the MAC data service.

6.5 PLME-SAP

The PHY layer management object service access points (MLME-PLME-SAP) enable the operational language between MLME and PLME. Additional physical layer management object service access points (DME-PLME-SAP) enable the operational language between DME and PLME, and this interface is equivalent to the MLME-PLME-SAP interface. Table 7 defines the primitives supported by PLME-SAP. Table 8 lays out the individual parameters.

Table 7 — PLME-SAP primitive summary

Name	Request	Confirm	Indication	Response
PLME-GET	6.6.1	6.6.2		
PLME-SET	6.6.3	6.6.4		
PLME-RESET	6.6.5	6.6.6		

Table 8 — PLME-SAP parameters

Name	Type	Valid range	Description
MIBAttribute	Enumeration		Desired physical layer MIB attribute
MIBStatus	Enumeration	SUCCESS, INVALID_ATTRIBUTE, INVALID_VALUE	Result of request for MIB attribute information
MIBAttributeValue	Various	Attribute specific	Desired physical layer MIB attribute value
ResetResult Code	Enumeration	SUCCESS, FAILED	Response to reset request

6.5.1 PLME-GET.request

This primitive requests Information about a PHY layer MIB attribute.

6.5.1.1 Definition of service primitives

The semantics of this primitive are:

```
PLME-GET.request (
    MIBAttribute
)
```

Table 8 define the parameter of this primitive.

6.5.1.2 When generated

This occurs by DME to obtain information from the PHY layer MIB of PLME..

6.5.1.3 Effect of receipt

The receipt of the PLME-GET.request primitive by the PHY entity extracts the requested MIB attribute from the database and sends the results through a PLME-GET.confirm primitive.

6.5.2 PLME-GET.confirm

This primitive report result of the requested information from the PHY layer MIB.

6.5.2.1 Definition of service primitives

The semantics of this primitive are:

```
PLME-GET.confirm (
    MIBstatus,
    MIBAttribute,
    MIBAttributeValue
)
```

Table 8 define the parameter of this primitive.

6.5.2.2 When generated

PLME generates this as a response to a PLME-GET.request primitive and sends it to DME.

6.5.2.3 Effect of receipt

If the state parameter is SUCCESS the requested PHY layer MIB value is sent, otherwise an error is indicated.

6.5.3 PLME-SET.request

This primitive request to set the PHY layer MIB attribute to the specified value.

6.5.3.1 Definition of service primitives

The semantics of this primitive are:

```
PLME-SET.request (
    MIBAttribute,
    MIBAttributeValue
)
```

Table 8 define the parameter of this primitive.

6.5.3.2 When generated

This occurs by DME to set the PHY layer MIB attribute to the specified value and sends it to PLME.

6.5.3.3 Effect of receipt

The receipt of the PLME-SET.request primitive by the PHY entity attempts to store the specified PHY layer MIB attribute in the database and reports the result through a PLME-SET.confirm primitive.

6.5.4 PLME-SET.confirm

This primitive reports result of the attempt to set the PHY layer MIB attribute to the specified value.

6.5.4.1 Definition of service primitives

The semantics of this primitive are:

```
PLME-SET.confirm (
    MIBstatus,
    MIBAttribute
)
```

Table 8 define the parameter of this primitive.

6.5.4.2 When generated

PLME sends this to DME as the response to the PLME-SET.request primitive.

6.5.4.3 Effect of receipt

If the state value is SUCCESS it means the MIB attribute was set as requested, otherwise an error is indicated if the MIB attribute was unable to be set for some reason.

6.5.5 PLME-RESET.request

This primitive requests a reset of the PHY layer.

6.5.5.1 Definition of service primitives

The semantics of this primitive are:

```
PLME-RESET.request    (
                        )
```

This primitive has no parameters.

6.5.5.2 When generated

This is generated whenever a PHY layer reset is requested.

6.5.5.3 Effect of receipt

The PHY layer resets all transceiver state machines to their initial states.

6.5.6 PLME-RESET.confirm

This primitive reports result of reset the PHY layer.

6.5.6.1 Definition of service primitives

The semantics of this primitive are:

```
PLME-RESET.confirm    (
                        ResetResultCode
                        )
```

Table 8 define the parameter of this primitive.

6.5.6.2 When generated

PLME generates this as the result of a PLME-RESET.request.

6.5.6.3 Effect of receipt

DME or MLME is notified of the result of the reset.

6.6 PD-SAP

The PD-SAP supports the transmission of MPDUs between peer MAC sublayer entities. Table 9 lists the primitives supported by the PD-SAP. These primitives are discussed in the subclauses referenced in the table.

Table 9 — PD-SAP primitives

Name	Request	Confirm	Indication	Response
PD-DATA	5.6.1	5.6.2	5.6.3	

Table 10 — PD-SAP parameters

Name	Type	Valid range	Description
psduLength	Unsigned Short Integer	$\leq$ aMaxPHYPacketSize	The number of octets contained in the PSDU received by the PHY entity.
psdu	Set of octets	-	The set of octets forming the PSDU received by the PHY entity.
status	Enumeration	SUCCESS (EoF)	The result of the request to transmit a packet.
rsi	Integer		RSSI Value

6.6.1 PD-DATA.request

This primitive requests the transmission of a MPDU from the MAC sublayer to the local PHY entity.

6.6.1.1 Definition of service primitives

The semantics of this primitive are:

```
PD-DATA.request  (
    psduLength,
    psdu
)
```

Table 10 define the parameter of this primitive.

6.6.1.2 When generated

This occurs when the MAC sublayer entity requests transmission of a MPDU to the PHY layer entity.

6.6.1.3 Effect of receipt

The receipt of the PD-DATA.request primitive by the PHY entity will cause the transmission of the supplied PSDU. When the PHY entity has completed the transmission, it will issue the PD-DATA.confirm primitive with a status of SUCCESS.

6.6.2 PD-DATA.confirm

This primitive confirm that the MAC sublayer entity has sent a MPDU (PSDU) to another MAC sublayer entity.

6.6.2.1 Definition of service primitives

The semantics of this primitive are:

```
PD-DATA.confirm  (
    status
)
```

Table 10 define the parameter of this primitive.

6.6.2.2 When generated

The PHY layer entity sends this primitive to the MAC sublayer entity as a response to the PD-DATA.request primitive when the requested PSDU is transmitted.

6.6.2.3 Effect of receipt

On receipt of the PD-DATA.confirm primitive, the MAC sublayer entity is notified of the result of its request to transmit. If the transmission attempt was successful, the status parameter is set to SUCCESS.

6.6.3 PD-DATA.indication

This primitive indicates the received PSDU from PHY layer to the MAC sublayer entity.

6.6.3.1 Definition of service primitives

The semantics of this primitive are:

```
PD-DATA.indication (
    psduLength,
    psdu
    rssi
)
```

Table 10 define the parameter of this primitive.

6.6.3.2 When generated

This occurs when the PHY layer sends the received PSDU to the MAC sublayer entity.

6.6.3.3 Effect of receipt

The receipt of the PD-DATA.indication primitive, the MAC sublayer is notified of the arrival of an MPDU across the PHY data service.

7 MAC PDU format

This clause specifies the formats of the MAC PDU (MPDU).

MAC frame consists of one control frame and one or more payload frames. Control frame is categorised into one of the six kinds depending on its use: (1) beacon frame (BF), (2) fast beacon frame (FBP), (3) request control frame (RCF), (4) master control frame (MCF), (5) RCF acknowledge control frame (RACF), and (6) MCF acknowledge control frame (MACF).

Figure 4 shows the relationship between MPDU and PPDU in a frame structure.

Figure 4 — MPDU in Frame structure

The format of each control frame is described in 7.1 through 7.6. The format of payload frame is described in 7.7.

7.1 MPDU of beacon frame (BF)

BFs are used to maintain synchronisation. There are two BF during a single normal superframe. The master sends information used for synchronisation, and the slaves acquire the synchronisation from BFs.

The MPDU format of BF is shown in Figure 5.

7.1.1 Open flag (OF, 2 bits)

This field provides information on whether an open code is applied to the current frame. This field comprises of GCOF which is used to indicate whether a group code is applied and SCOF which is used to indicate whether a security code is applied. That GCOF is 1 means an open group code is applied. When it is 0, a closed group code is applied. That SCOF is 1 means an open security code is applied. When it is 0, a closed security code is applied.

7.1.2 MAC version (6 bits)

This field provides information about the MAC Version, and has a value between 0x00 to 0x3F.

7.1.3 Address mode (ADDM, 2 bits)

This field provides information about whether a MAC address exists. The ADDM comprises of two bits: one bit used for displaying whether a source MAC address exists and the other bit used for displaying the destination MAC address.

7.1.4 PHY version (6 bits)

This field provides information about the PHY version, and has a value between 0x00 to 0x3F.

7.1.5 Frame type (8 bits)

This field is used for displaying the BF Type.

7.1.6 Superframe mode control (SFMC, 2 bits)

This field is used for selecting a mode of the superframe. It comprises of the current superframe mode (CSFM) and the next superframe mode (NSFM). That CSFM is 1 means the current superframe is a normal superframe. When it is 0, the current superframe is a fast synchronisation superframe. That NSFM is 1 means the next superframe is a normal superframe. When it is 0, the current superframe is a fast synchronisation superframe.

7.1.7 Upper layer frame size (ULFS, 6 bits)

This field provides information on the size of the data from the upper layer.

7.1.8 Source MAC address (64 bits)

This field provides the MAC address of the master which is sending BFs.

7.1.9 Superframe counter (SFC, 4 bits)

This field provides information on the superframe counter. The value circulates from 0 to 15.

Figure 5 — MPDU format of Beacon Frame

7.1.10 Middleframe counter (FC, 4 bits)

This field provides information on the middleframe counter. The value circulates from 0 to 15.

7.1.11 Hopping sequence (32 bits)

This field provides the hopping sequence of the frequencies that were chosen for communication.

7.1.12 BF frequency table (BFFT, 16 bytes)

This field provides information on the sequence of the frequencies used for the partial band hopping. BFFT contains a table of 16 frequencies being used for communication.

7.1.13 Upper layer data (16 bytes)

This field is used for transmission of the data from the upper layer.

7.2 MPDU of fast beacon frame (FBF)

This field is used for initial fast synchronisation. There are 16 FBFs in a single fast synchronisation superframe. The master sends information for synchronisation in the FBFs, and the slaves are synchronised using these FBFs.

The MPDU format of FBF is shown in Figure 6.

7.2.1 Open flag (OF, 2 bits)

This field provides information on whether an open code is applied to the current frame. This field comprises of GCOF which is used to indicate whether a group code is applied and SCOF which is used to indicate whether a security code is applied. That GCOF is 1 means an open group code is applied. When it is 0, a closed group code is applied. That SCOF is 1 means an open security code is applied. When it is 0, a closed security code is applied.

7.2.2 MAC version (6 bits)

This field provides information on the MAC version, and has a value between 0x00 to 0x3F.

7.2.3 Address mode (ADDM, 2 bits)

This field provides information on whether MAC addresses exist. The ADDM comprises of two bits: one bit is used to indicate whether a source MAC address exists and the other bit is used to indicate whether a destination MAC address exists. One means an address exists.

7.2.4 PHY version (6 bits)

This field provides information on the PHY version, and has a value between 0x00 to 0x3F.

7.2.5 Frame type (8 bits)

This field is used to indicate the type of the current frame.

7.2.6 Superframe mode control (SFMC, 2 bits)

This field is used for selecting the mode of the superframe. It comprises of the current superframe mode (CSFM) and the next superframe mode (NSFM). That CSFM is 1 means the current superframe is a normal superframe. When it is 0, the current superframe is a fast synchronisation superframe. That NSFM is 1 means the next superframe is a normal superframe. When it is 0, the next superframe is a fast synchronisation superframe.

7.2.7 Upper layer frame size (ULFS, 6 bits)

This field provides information on the size of the data from the upper layer.

7.2.8 Source MAC address (64 bits)

This field provides the MAC address of the master which is sending BF.

7.2.9 Superframe counter (SFC, 4 bits)

This field provides information on the superframe counter. The value circulates from 0 to 15.

Figure 6 — MPDU format of Fast Beacon Frame (FBF)

7.2.10 Middleframe counter (SC, 4 bits)

This field provides information on the middleframe counter. The value circulates from 0 to 15.

7.2.11 Hopping sequence (32 bits)

This field provides the hopping sequence of the frequencies that were chosen for communication.

7.2.12 BF frequency table (BFFT, 16 bytes)

This field provides information on the sequence of the frequencies used for the partial band hopping. BFFT contains a table of 16 frequencies being used for communication.

7.2.13 Upper layer data (16 Bytes)

This field is used for transmission of the data from the upper layer.

7.3 MPDU of request control frame (RCF)

RCFs are used to exchange control information between devices. In response to RCF, Acknowledge Control Frame of RCF (RACF) is issued. The RCF is used for multiple simultaneous communications among devices in a group. When two or more devices initiate communications at the same time, there may be collision. To ensure reliability of the control information, the random back off must be devised to resolve collisions. All the devices must be either in transmission mode or in reception mode.

The MPDU format of RCF is shown in Figure 7.

7.3.1 Open flag (OF, 2 bits)

This field provides information on whether an open code is applied to the current frame. It comprises of GCOF which is used to indicate whether a group code is applied and SCOF which is used to indicate whether a security code is applied. That GCOF is 1 means an open group code is applied. When it is 0, a closed group code is applied. That SCOF is 1 means an open security code is applied. When it is 0, a closed security code is applied.

7.3.2 MAC version (6 bits)

This field provides information on the MAC Version, and has a value between 0x00 to 0x3F.

7.3.3 Address mode (ADDM, 2 bits)

This field provides information on whether MAC addresses exist. The ADDM comprises of two bits: one bit is used to indicate whether a source MAC address exists and the other bit is used to indicate whether a destination MAC address exists.

7.3.4 PHY version (6 bits)

This field provides information on the PHY Version, and has a value between 0x00 to 0x3F.

7.3.5 Frame type (8 bits)

This field is used to indicate the type of the current frame.

7.3.6 Upper layer frame size (ULFS, 6 bits)

This field provides information on the size of the data from the upper layer.

7.3.7 Source MAC address (64 bits)

This field provides the MAC address of the device which is sending RCFs.

7.3.8 Destination MAC address (64 bits)

This field provides the MAC address of the device which is to receive RCFs.

7.3.9 Upper layer data

This field is used for transmission of the data from the upper layer.

Figure 7 — MPDU format of RCF

7.4 MPDU of master control frame (MCF)

MCFs are used by the master in a group to send control information to slaves. The master can send control information up to 8 devices by using a single MCF. Slave devices may respond to MCF using the frames called MACF (MCF acknowledgement control frame). MACFs are issued by the responding slaves as controlled by MCFs in a manner to avoid collision. Each responding slave takes up a different MACF slot.

The MPDU format of MCF is shown in Figure 8.

7.4.1 Open flag (OF, 2 bits)

This field provides information on whether an open code is applied to the current frame. It comprises of GCOF which is used to indicate whether a group code is applied and SCOF which is used to indicate whether a security code is applied. That GCOF is 1 means an open group code is applied. When it is 0, a closed group code is applied. That SCOF is 1 means an open security code is applied. When it is 0, a closed security code is applied.

7.4.2 MAC version (6 bits)

This field provides information on the MAC version, and has a value between 0x00 to 0x3F.

Figure 8 — MPDU format of MCF

7.4.3 Address mode (ADDM, 2 bits)

This field provides information on whether MAC addresses exist. The ADDM comprises of two bits: one bit is used to indicate whether a source MAC address exists and the other bit is used to indicate whether a destination MAC address exists.

7.4.4 PHY version (6 bits)

This field provides information on the PHY Version, and has a value between 0x00 to 0x3F.

7.4.5 Frame type (8 bits)

This field is used to indicate the type of the current frame.

7.4.6 Upper layer frame size (ULFS, 6 bits)

This field provides information on the size of the data from the upper layer.

7.4.7 Source MAC address (64 bits)

This field provides the MAC address of the master which is sending MCFs.

7.4.8 Destination MAC address (64 bits)

This field provides the MAC address of the device which is to receive MCFs.

7.4.9 Upper layer data

This field is used for transmission of the data from the upper layer.

7.5 MPDU of RCF acknowledge control frame (RACF)

A device receiving RCFs sends RACFs in response. The device that sent RCFs receives RACFs as an acknowledgement. RACFs are control frames that can be sent to both the master and the slave devices. After sending RCF, when a RACF response is not received as is necessary, RCF may be re-sent after backing off in random superframe units.

The MPDU format of RACF is identical to that of RCF except for the Frame Type field.

7.6 MPDU of MCF acknowledge control frame (MACF)

MACFs are issued by the slaves that need to acknowledge the reception of MCFs. The master checks MACFs to verify responses from the slaves with respect to MCFs.

The MPDU format of MACF is identical to that of MCF except for the Frame Type field.

7.7 MPDU of payload frame (PF)

Payload frames are used to transmit data from upper layers. The number of payload frames may vary depending on the requirement of upper layers. The number may be from one to eighteen.

The MPDU format of PF is shown in Figure 9.

7.7.1 Open flag (OF, 2 bits)

This field provides information on whether an open code is applied to the current frame. It comprises of GCOF which is used to indicate whether a group code is applied and SCOF which is used to indicate whether a security code is applied. That GCOF is 1 means an open group code is applied. When it is 0, a closed group code is applied. That SCOF is 1 means an open security code is applied. When it is 0, a closed security code is applied.

7.7.2 MAC version (6 bits)

This field provides information on the MAC version, and has a value between 0x00 to 0x3F.

7.7.3 Address mode (ADDM, 2 bits)

This field provides information on whether MAC addresses exist. The ADDM comprises of two bits: one bit is used to indicate whether a source MAC address exists and the other bit is used to indicate whether a destination MAC address exists.

7.7.4 PHY version (6 bits)

This field provides information on the PHY Version, and has a value between 0x00 to 0x3F.

7.7.5 Frame type (8 bits)

This field is used to indicate the type of the current frame.

Figure 9 — MPDU format of PF

7.7.6 Upper layer frame size (ULFS, 6 bits)

This field provides information on the size of the data from the upper layer.

7.7.7 Source MAC address (64 bits)

This field provides the MAC address of the device which is sending PFs.

7.7.8 Destination MAC address (64 bits)

This field provides the MAC address of device which is to receive PFs.

7.7.9 Upper layer data

This field is used for transmission of the data from the upper layer.

8 MAC functional description

This clause describes the functions of the MAC layer.

8.1 General description

In communications in a pico-net, it is required to keep the devices within the pico-net synchronised. For this purpose, in a pico-net, one device must operate as a master, which sends synchronising signals periodically, and the other devices operate as slaves in accordance with the synchronizing signals from the master.

Figure 10 shows a pico-net with only two terminals. One terminal must serve as a master while the other as a slave. The master regularly transmits synchronising signals to which the slave is synchronised. Communications between the two terminals are based on this synchronisation.

Figure 11 shows a pico-net with more than two devices. One device must serve as a master while the others as slaves. All the devices must be synchronised to the master's synchronising signals. Communications between any two or more devices are practiced based on this synchronisation with no further master's intervention. The master transmits synchronising signals only to maintain the synchronisation within the network. Communications between slaves are practiced directly without the master's relaying the communications.

8.2 System state diagram

The master/slave operations can be expressed as a finite state machine with 10-phase states. Any device is in one of the ten states. The description of the ten states is summarised in Table 11.

Table 11 — Description of states

State	Description
Not initialised	A state before initialisation.
Initialised	A state after initialisation is completed; the master and slaves are determined.
Normal master sync.	A state where the device is serving as the master of the normal superframe.
Fast master sync.	A state where the device is serving as the master of the fast synchronisation superframe.
Scanning	A state where the device is under synchronisation with the master.
Normal slave sync.	A state where the device is serving as a slave in the normal superframe after synchronisation with the master.
Fast slave sync.	A state where the device is serving as a slave in the fast synchronisation superframe after synchronisation with the master.
Passive sounding	A state where the master conducts passive sounding.
Master static sounding	A state where the master conducts static sounding.
Slave static sounding	A state where the slave conducts static sounding

Figure 12 shows the state-transition diagram. The solid line and the dotted line represent the paths of the state changes of the master and the slaves, respectively.

The network operation begins with initialisation. The initialisation starts when more than two devices within the communication range are first turned on.

When the initialisation starts, the master performs the initialisation process, regardless of whatever state it has been in. After initialisation is completed, the master stays in the 'initialised' state. The master in the 'initialised' state can shift into the 'passive sounding' or 'normal/fast master sync' state.

Passive sounding is a state where frequencies are selected by measuring the signal level at each frequency. The master may choose to put itself into the 'passive sounding' state if needed.

After shifting into the 'normal/fast master sync' state, the master sends synchronising signals. In these states, the master can communicate with the slaves synchronised with the synchronising signals. In the 'master sync' states, the master can shift into the 'static sounding' state where frequencies can be selected via special communication between the master and the slaves. In the 'static sounding' state, normal communications between the master and the slaves cannot be practiced. The 'static sounding' state can be selected by the user whenever needed.

After initialisation with the master, the slaves are forced into the 'initialised' state. The slaves are forced into initialisation process once initialisation process is initiated, regardless of whatever state they have been in. The slaves synchronise with the master in the 'scanning' state after initialisation. With the synchronisation information from the master, the slaves synchronise with the master and shift into the 'normal/fast slave sync' state. When the synchronisation information is not obtained, the slaves are again put into the 'initialized' state. After the slaves are synchronised with the master and put into the 'normal/fast slave sync' state, the slaves

Figure 12 — State transition diagram

can communicate with the master. When a static sounding is requested from the master, the slaves shift into the 'static sounding' state to conduct static sounding.

8.3 Protocol structure

Figure 13 shows the hierarchical structure of the protocol. The protocol is structured based on the superframes of 256 msec each, which again consists of 16 middleframes of 16msec each. A middleframe consists of one control frame and one or more payload frames.

The middleframe is the most basic unit structure. The state of each middleframe can be set independently of the others.

The number of payload frames is determined based on the communication type (data, voice, control, etc). However, it is required to maintain the length of superframes equal for synchronised communication. The synchronisation between devices is possible only if the lengths of all superframes are equal. The synchronised communications minimize the frequency interference between devices of different services by controlling the transmission and reception based on time slots.

Figure 13 — The protocol structure

8.3.1 Middleframe structure

Figure 14 shows the structure of the middleframe. A middleframe consists of one control frame and one or more payload frames. The length of the control frame is fixed at 880 μ sec. The number and length of payload frames within a middleframe can be set as needed. The upper layers may have various data rates depending on the number and length of the payload frames. When high data rate is needed, the number of payload frames can be reduced to lower overhead. However, transmission delay due to buffering increases in proportion to the length of middleframe. The number of payload frames must be between 1 and 18. The total length of all payload frames should be 15,12 msec.

Figure 14 — Middleframe structure

8.3.2 Superframe structure

The length of a single superframe is 256 msec; the superframe consists of 16 frames. Within a superframe are 16 control frames of 0,88 msec each. Overall, 14,08 msec is assigned to control frames and the rest 241,92 msec to payload frame(s). Each control frame has its own unique function as described in section 7. There are two types of superframe: a normal superframe and a fast synchronisation superframe.

8.3.2.1 Normal superframe

Figure 15 shows the structure of a normal superframe. There are 16 control frames in a normal superframe: two are beacon frames (BF), one is a request control frame (RCF) used when slaves send request information to the master, one is a master control frame (MCF) used when the master sends control information to the slaves, one is allocated for response to RCF, eight for response to MCF, and the remaining three are reserved.

Figure 15 — Structure of a normal superframe

8.3.2.2 Fast synchronisation superframe

Figure 16 shows the structure of a fast synchronisation superframe. For a fast synchronisation, a fast synchronisation superframe should be adopted. All control frames in the fast synchronisation superframe are used for synchronisation. These control frames used for synchronisation are called fast beacon frames (FBFs).

Figure 16 — Structure of a fast synchronisation superframe

8.3.2.3 Alternation between superframes

For a normal operation, the normal superframe repeats itself. For a fast synchronisation, alternation between a normal superframe and a fast synchronisation superframe is practiced. Figure 17 illustrates the operation of the fast synchronisation.

Figure 17 — Superframe mode alternation

8.3.2.4 Middleframe counter and superframe counter

Numbers are assigned to the middleframes and superframes to maintain the structure. The counters are in the message field of each beacon frame or fast beacon frame. A number '0' is assigned to the first middleframe in a superframe. The number increases by one in the frames that follow. A number '15' is assigned to the last middleframe in the superframe. Likewise, a number is assigned to each superframe, which repeats itself with a period of 16. The number starts with 0 and ends with 15. Figure 18, 19 shows the middleframe and superframe counters, respectively.
