Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take Part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 10110-8 was prepared by Technical Committee ISO/TC 172, *Optics and photonics*, Subcommittee SC 1, *Fundamental standards*.

This second edition cancels and replaces the first edition (ISO 10110-8:1997), which has been technically revised.

ISO 10110 consists of the following parts, under the general title *Optics and photonics — Preparation of drawings for optical elements and systems*:

- *Part 1: General*
- *Part 2: Material imperfections — Stress birefringence*
- *Part 3: Material imperfections — Bubbles and inclusions*
- *Part 4: Material imperfections — Inhomogeneity and striae*
- *Part 5: Surface form tolerances*
- *Part 6: Centring tolerances*
- *Part 7: Surface imperfection tolerances*
- *Part 8: Surface texture; roughness and waviness*
- *Part 9: Surface treatment and coating*
- *Part 10: Table representing data of optical elements and cemented assemblies*
- *Part 11: Non-toleranced data*
- *Part 12: Aspheric surfaces*
- *Part 14: Wavefront deformation tolerance*
- *Part 17: Laser irradiation damage threshold*

Optics and photonics — Preparation of drawings for optical elements and systems —

Part 8: Surface texture; roughness and waviness

1 Scope

ISO 10110 specifies the presentation of design and functional requirements for optical elements in technical drawings used for manufacturing and inspection.

This part of ISO 10110 specifies rules for the indication of the surface texture of optical elements. Surface texture is the characteristic of a surface that can be effectively described with statistical methods. Typically, surface texture is associated with high spatial frequency errors (roughness) and mid-spatial frequency errors (waviness).

This part of ISO 10110 is primarily intended for the specification of polished optics.

This part of ISO 10110 describes a method for characterizing the residual surface that is left after detrending by subtracting the surface form. The control of the surface form is specified in ISO 10110-5 and ISO 10110-12, it is not specified in this part of ISO 10110.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO 1302:2002, *Geometrical Product Specifications (GPS) — Indication of surface texture in technical product documentation*

ISO 4287:1997, *Geometrical Product Specifications (GPS) — Surface texture: Profile method — Terms, definitions and surface texture parameters*

3 Terms and definitions

For the purposes of this document, terms and definitions given in ISO 4287 and the following apply.

3.1

surface texture

characteristic relating to the profile of an optical surface that can be effectively described with statistical methods

NOTE Localized defects, known as surface imperfections, are specified in ISO 10110-7.

3.2

matt surface

optical surface for which the height variation of the surface texture is not considerably smaller than the wavelength of light

NOTE Matt surfaces are usually produced by brittle grinding of glass or other dielectric material, or by etching.

3.3

optically smooth surface

optical surface for which the height variation of the surface texture is considerably smaller than the wavelength of light

NOTE 1 Due to the smaller height variation, the amount of light scattered is small.

NOTE 2 Optically smooth surfaces are usually produced by polishing or moulding.

3.4

microdefect

small irregularity in an optically smooth surface; i.e. location where the surface height differs from the average surface height by more than twice the standard deviation

NOTE Usually, microdefects are pits remaining after an incomplete polish, although they can also be due to mishandling and contamination during polishing. Microdefects are of concern because they produce large-angle scattering. Microdefects are not considered surface imperfections as treated in ISO 10110-7 because they are usually reasonably uniformly distributed over the surface and thus have a global characteristic associated with texture.

3.5

detrending

fitting and removing a surface form from a set of measured data

NOTE 1 Detrending is usually applied to the input data to avoid masking low-amplitude high frequency errors with the large amplitude, low frequency surface form errors. The resultant set of data points represents the residual surface.

NOTE 2 For the purposes of this part of ISO 10110, the surface form used for detrending is a polynomial fit to the measured surface with an order sufficient to remove all spatial wavelengths longer than the spatial bandwidth of the specification.

3.6

measured surface

Z_m

function of raw surface measurement data, prior to detrending

3.7

surface form

Z_f

fit to a measured surface

NOTE In a typical 2D polynomial fit to a surface, the surface polynomial can be written as a Zernike polynomial or another polynomial equation. For example in Cartesian coordinates:

$$Z_f(x, y) = \sum_{i=1}^p \sum_{j=1}^q C_{ij} P_{ij}(x, y) \quad (1)$$

where P_{ij} is a polynomial function of order p, q that describes the underlying shape of the surface.

3.8**residual surface** Z

function that is calculated by subtracting the surface form Z_f from a measured surface Z_m

NOTE 1 For example in 2D, this is expressed mathematically as: $Z(x,y) = Z_m(x,y) - Z_f(x,y)$ or in polar coordinates $Z(r,\theta) = Z_m(r,\theta) - Z_f(r,\theta)$.

NOTE 2 Neglecting correction factors for instrument response, the residual surface is taken as the surface height data.

3.9**sampled surface data**

residual surface data, $Z(x_m, y_n)$, sampled on a discrete m by n grid of points (x_m, y_n)

3.10**evaluation length**

length over which the surface texture is to be evaluated

NOTE Typically this is synonymous with trace length in a profile measurement. The default evaluation length is five times the upper limit of the spatial bandwidth.

3.11**spatial wavelength**

peak to peak scale-length of a sinusoidal surface undulation, especially when viewed in a Fourier transform

NOTE See ISO 3274 and ISO 11562 for more information.

3.12**spatial bandwidth**

range of surface spatial wavelengths which are to be included in the specification

NOTE This is equivalent to the term "transmission band" as used in ISO 1302. In order to prevent confusion with spectral transmission bands, the term "spatial bandwidth" is used instead of "transmission band" in this part of ISO 10110.

3.13**root mean square roughness****rms roughness** R_q

square root of the mean of the square of the residual surface height in a region for short spatial wavelengths

3.14**root mean square waviness****rms waviness** W_q

square root of the mean of the square of the residual surface height in a region for spatial wavelengths between those of surface roughness and surface form

3.15**power spectral density****PSD**

squared magnitude of the Fourier transform of the residual surface height function along one dimension using an appropriate weighting function

3.16**surface lay symbol**

symbol indicating the lay of the surface profile parameter

NOTE According to ISO 1302:2002, Table 2, the following symbols are used for surface lay; R (radial), C (circular), X (crossed), = (parallel to projection), $\perp$ (perpendicular to projection), etc.

3.17

local slope

Δ

difference between the heights at two points on the residual surface, divided by the distance between the points

NOTE 1 The local slope is expressed in microradians.

NOTE 2 In one dimension, the surface slope points can be computed directly from the surface heights by successive differences:

$$\Delta(x_n) = \frac{1}{dx} [Z(x_{n+1}) - Z(x_n)] \text{ where } n = 1, 2, \dots, n-1 \quad (2)$$

NOTE 3 This differencing calculation always results in one less data point in the slope profile.

NOTE 4 This is the equivalent of the property symbolized by dZ/dX in ISO 4287:1997, but generalized so that it can be calculated along any direction or lay and in any coordinate system.

3.18

root mean square slope

rms slope

$R\Delta q$

square root of the mean of the square of the local slopes in a region on a residual surface

NOTE The root mean square slope is expressed in microradians.

4 Description of surface texture

4.1 General

Surface texture is a global statistical characteristic of the profile of the optical surface, and it is assumed for this part of ISO 10110 that the character and magnitude of the texture in any one area of the surface is similar to that in all other areas of the same surface. This assumption is made so that a measurement made in one part of an indicated test region or surface may be considered representative of the entire test region or surface.

Unless stated otherwise, the indication of surface texture applies to surfaces before coating. This is an exception to the general statement in ISO 10110-1:2006, Clause 3, paragraph 1.

Materials having a crystal structure and production processes such as diamond turning can give rise to non-random surface texture. Care should be used in applying statistical surface properties for surface texture with these types of surfaces.

Because the magnitude of the measured roughness is a function of the spatial wavelengths considered, this part of ISO 10110 provides for the indication of the spatial bandwidth.

This part of ISO 10110 makes use of the terminology of profilometry, as specified in ISO 4287. Although the main effect of surface roughness is optical scattering, no reference is made to scattering measurements because there are causes of scattering other than texture (details of the relationship between surface texture and optical scattering are given in the Bibliography). Although the terminology in this part of ISO 10110 is that of profilometry, areal measurements (that is, measurements over a specified area) can also be used to characterise surface texture.

Surface texture specifications are applicable to matt surfaces as well as to optically smooth surfaces made by polishing or moulding. In this part of ISO 10110, texture also refers to microdefects, such as pits left from an incomplete polish, that are nominally uniformly distributed over a smooth surface. Surface texture also refers to other statistical properties of the surface of longer scale-lengths, such as mid-spatial frequency waviness, which can be specified using root mean square (rms) roughness, rms slope, PSD and other statistical methods.

Depending on the application of a surface and the magnitude of surface height variation, one or more methods outlined below may be appropriate for describing surface texture numerically.

In calculating any statistical surface property, care should be taken regarding the spatial wavelength ranges over which the calculation is to be made. Both limits of the spatial band, in a long-scale length sense and a short-scale length sense, should be carefully considered. Significant errors can be introduced in the process of bandpass filtering or detrending of surface height data.

NOTE Computing the slope between adjacent sampled height points results in a large rms slope number that is usually dominated by instrument noise. To suppress the high frequency slope bias, one needs to first filter the height data with a low-pass filter before differentiating the height profile. The rms slope computed from this filtered data is equivalent to computing the rms slope from the slope PSD over a spatial bandwidth equivalent to the filter cutoff.

4.2 Description of matt surfaces

Matt surfaces shall be specified by indication of the rms height variation, R_q (see ISO 4287:1997, 4.2.2). This quantity depends on the range of spatial wavelengths to be considered. For this reason it may be necessary to specify the lower and upper limits of the spatial bandwidth.

If no spatial bandwidth is specified, the spatial bandwidth is assumed to be 0,002 5 mm to 0,08 mm.

In some cases, functional requirements may dictate a roughness criterion other than R_q . In such cases, that other criterion shall be indicated as shown in ISO 1302:2002.

4.3 Description of optically smooth surfaces

4.3.1 Description methods

There are five statistical methods of describing optically smooth surfaces:

- a) by means of the rms roughness, R_q ;
- b) by rms waviness, W_q ;
- c) by indication of the density of microdefects;
- d) by using a power spectral density (PSD) function;
- e) by specifying the rms slope.

These methods can be used in combination, and can be used over various spatial bandwidths in the same region.

4.3.2 Rms roughness and rms waviness

Optically smooth surfaces are commonly specified by indication of the rms roughness, R_q . For longer spatial wavelength ranges, the rms waviness, W_q , is used.

If the surface height variations obey certain statistical distribution properties, the rms value, R_q , can be related to the magnitude of the optical scattering (see Annex B). Note that the rms description is incomplete without indicating the spatial bandwidth limits.

In the event that no spatial bandwidth is specified, the spatial bandwidth is assumed to be 0,002 5 mm to 0,08 mm for R_q and 0,08 mm to 2,5 mm for W_q .

NOTE These default values can be significantly different depending on the requirements for R_q or W_q . Therefore, the correct requirements for R_q or W_q are necessary to ensure that they are consistent with the spatial bandwidth of the specification.

4.3.3 Quantification of microdefects

Microdefects can be understood as being very localized pits in an optically smooth surface. They are quantified by lightly drawing a sharp stylus of a mechanical profilometer across the surface to be measured and noting the number of times, N , that the stylus deviates markedly from the otherwise smooth profile in a 10 mm long scan, which is presumed to have a measurement width of order 1 μm . An optical profilometer, a microscope or a microscopic image comparator may also be used to quantify microdefects. The number of microdefects, N , is taken to be over a 10 mm line scan with resolution of 3 μm , or an area of 300 $\mu\text{m} \times 300 \mu\text{m}$ with the same resolution.

4.3.4 Power spectral density (PSD) function

The PSD function is directly related to the frequency spectrum of the surface roughness. It allows a complete description of the surface texture characteristics, and is particularly useful for specifying supersmooth surfaces used in high technology applications, or in controlling mid-spatial frequency waviness on a surface. The PSD function description places no restrictions on the nature of, or the statistical properties of, the measured surface.

In the one-dimensional case, i.e. when the surface texture can be determined by measurement along a line on the surface, the PSD, expressed in $\text{nm}^2 \times \text{mm}$, can be modelled by Equation (3):

$$\text{PSD} = \frac{A}{f^B} \quad \text{for } \frac{1}{D} < f < \frac{1}{C} \quad (3)$$

where

f is the spatial frequency of the roughness or waviness, in inverse millimetres (mm^{-1});

B is the power to which the spatial frequency is raised;

C and D are the limits of the spatial bandwidth, in millimetres;

A is a constant.

The value of B shall be greater than zero. (For many real surfaces, $1 < B < 3$, see Reference [9]).

In this way, the surface texture requirement may be given by specifying the four values A , B , C and D , for which Equation (3) shall hold.

This one dimensional PSD can be calculated for any line of data. Such a line of data can be generated from 1D surface profilometry, or by averaging multiple lines of 1D surface profilometry, or by averaging an areal image along any axis. In the event that the directionality of the PSD is considered significant, a surface lay symbol is added to the surface texture specification.

NOTE 1 The cartesian 1D PSD of a 2D residual surface can be calculated from sampled surface data by averaging $Z(x,y)$ for all values of x to create an equivalent line trace $Z(y)$, or alternatively averaging $Z(x,y)$ for all values of y to create an equivalent line trace $Z(x)$. These line traces can be used as 1D residual data for PSD calculations.

NOTE 2 The polar coordinate 1D PSD of a 2D residual surface can be calculated by averaging $Z(r,\theta)$ for all values of ρ to create an equivalent line trace $Z(r)$, and then averaging $Z(r,\theta)$ for all values of r to create an equivalent line trace $Z(\theta)$. These line traces can be used as 1D residual data for PSD calculations.

In the event that no spatial bandwidth is specified, the PSD is expected to be evaluated with a spatial bandwidth of 0,08 mm to 2,5 mm.

It is recommended that both limits of the spatial bandwidth are indicated in drawings, since spatial bandwidths depend on the applications, wavelengths of use, and measurement equipment available.

4.3.5 Rms slope

Optically smooth surfaces can also be specified by indication of the root mean square slope, $R\Delta q$.

If the surface slope variations obey certain statistical distribution properties, the rms value, $R\Delta q$, can be related to the image quality, see Reference [10]. Note that the rms slope description is incomplete without indicating the spatial bandwidth limits.

In the event that no spatial bandwidth is specified, the surface slope spatial bandwidth is assumed to be 0,08 mm to 2,5 mm.

5 Indication in drawings

5.1 General

The symbols for indicating surface texture in drawings shall be in accordance with ISO 1302, if necessary, they can be modified as described below.

5.2 Indication for matt surface texture

The matt surface texture is indicated according to ISO 1302:2002, Clause 5, with the addition of the letter G [for "Ground"¹⁾] above the horizontal line, as shown in Figure 1. The maximum permissible rms roughness R_q in micrometres, is indicated under the horizontal line. When a single value of R_q is given, it represents the upper limit of the surface roughness parameter. When the roughness is not permitted to lie below a certain value the upper and lower limits of the rms roughness is indicated with a bilateral tolerance according to ISO 1302: 2002, 6.6. The upper limit of the rms roughness is identified with "U", and the lower limit is identified with "L". See Figure 1.

The spatial bandwidth may be indicated under the horizontal line, as shown in Figure 4. The upper limit is separated from the lower limit by a hyphen, and the spatial bandwidth is separated from the R_q notation by an oblique stroke (/). Spatial bandwidth limits shall be expressed in millimetres.

In the event that only the upper limit of the spatial bandwidth is to be specified, it is given as shown in Figure 1, after the hyphen.

EXAMPLE 1 0,002 5–0,8/ R_q 2 (example where the spatial bandwidth is specified); see Annex C.

EXAMPLE 2 –0,8/ R_q 2 (example where only the upper limit of the spatial bandwidth is specified); see Annex C.

NOTE The default evaluation length is five times the upper limit of the spatial bandwidth.

Figure 1 — Indication for matt surface texture with $0,05 \mu\text{m} \leq R_q \leq 2 \mu\text{m}$ and an upper limit of spatial bandwidth of 5 mm

1) The letter "G" is used to denote all matt surfaces, including those not produced by brittle grinding, e.g. etching.

5.3 Indication for optically smooth surface texture

5.3.1 Optically smooth surface without quantitative modification

The indication for optically smooth surface texture shall include the letter P [for “Polished”²⁾] above the horizontal line, as shown in Figure 2. The use of the letter P alone means that no quantification of the microdefects is required but that the surface shall be smooth.

Figure 2 — Indication for optically smooth surface texture without quantitative modifiers

5.3.2 Indication of polishing grade in terms of microdefects

The number of allowed microdefects is indicated by placing a grade number between 1 and 4 to the right of the letter P, as shown in Figure 3. The range of the corresponding permissible number of microdefects is given by grade in Table 1.

Figure 3 — Indication for optically smooth surface with quantitative modifiers; polishing grade with < 80 microdefects per 10 mm linear scan of the surface

Table 1 — Indication of the degree of smoothness in terms of microdefects

Polishing grade designation	Number, N , of microdefects per 10 mm of sampling length
P1	$80 \leq N < 400$
P2	$16 \leq N < 80$
P3	$3 \leq N < 16$
P4	$N < 3$

2) The letter “P” is used to indicate all optically smooth surfaces, including those not produced by polishing, e.g. moulded or float glass surfaces.

5.3.3 Indication of rms roughness and rms waviness

The rms roughness R_q or the rms waviness W_q is indicated by placing the maximum permissible value of the rms, expressed in micrometers, under the horizontal line, as shown in Figure 4.

Figure 4 — Indication for optically smooth surface with quantitative modifiers; polishing grade of < 16 microdefects per 10 mm scan and $R_q \leq 0,005 \mu\text{m}$ over a spatial bandwidth of 0,002 mm to 1 mm

A lower limit of the spatial bandwidth or alternatively a spatial bandwidth may be indicated under the horizontal line, separated from the indication for rms roughness or rms waviness by an oblique stroke (/). Limits of spatial bandwidths shall be given in mm.

EXAMPLE 1 $-1,0/R_q 0,002$ (surface roughness with only the upper limit of spatial bandwidth); see Annex C

EXAMPLE 2 $0,002-1,0/R_q 0,002$ (surface roughness with spatial bandwidth); see Annex C

EXAMPLE 3 $0,5-2,5/W_q 0,002$ (surface waviness with spatial bandwidth); see Annex C

NOTE The evaluation length is five times the minimum sampling length.

This indication can be complemented by an indication of the polishing grade in terms of microdefects according to 5.3.2.

5.3.4 Indication of PSD function specification

The maximum permissible value of the PSD function is indicated by placing the letters PSD and the values for A and B , as defined in 4.3.4 and separated by an oblique stroke (/), under the horizontal line, as shown in Figure 5. The upper and lower limits of the spatial bandwidth, C and D , expressed in millimetres, are placed under the horizontal line separated from the PSD note by an oblique stroke (/), as shown in Figure 5.

This indication can be complemented by an indication of the polishing grade in terms of microdefects in accordance with 5.3.2.

Figure 5 — Indication for an optically smooth surface; $\text{PSD} \leq 1,0/f^2 \text{ (nm}^2 \times \text{mm)}$ over a spatial bandwidth of 0,001 mm to 1 mm

5.3.5 Indication of rms slope specification

The rms slope $R\Delta q$ is indicated by placing the maximum permissible value of the rms slope, expressed in microradians, under the horizontal line as shown in Figure 6.

Figure 6 — Indication for an optically smooth surface; rms slope of $\leq 0,7 \mu\text{rad}$ for a spatial bandwidth of 0,01 mm to 5 mm

A spatial bandwidth may be indicated under the horizontal line, as shown in Figure 6. Spatial bandwidths shall be expressed in millimetres.

5.3.6 Indication of lay

In the event that the orientation of the surface texture parameter is significant, the addition of a surface lay symbol can be used. The letter C indicates a circular lay, while the letter R indicates a radial lay, as shown in Figure 7. Additional lay symbols are given in ISO 1302:2002, Table 2. If no indication of lay is given, then the surface parameter is assumed to apply for all orientations.

On rotationally symmetric parts, the lay indications C and R (for circular and radial) are recommended. On square or rectangular parts, the lay indications $\parallel$ and $\perp$ are recommended.

Figure 7 — Indication for optically smooth surface with $Wq \leq 0,005 \mu\text{m}$ for a spatial bandwidth of 0,01 mm to 5 mm, evaluated radially and circularly

5.4 Location

The tip of the texture symbol shall be in contact with the line representing the surface or with a corresponding subsidiary line (see Figures 1 to 6, as well as the examples given in ISO 10110-1:2006, Annex A). In tabular drawings (see also ISO 10110-10), the texture symbol and indication can be shown either in the drawing field or in the appropriate surface fields. In the event that the surface texture of all surfaces are the same, the texture can be indicated in a note.

Annex A

(informative)

Specification of texture for optically smooth surfaces in terms of microdefects

The fundamental investigation of microdefects is described in Reference [11].

An estimation of the expected correlation between polishing grades and surface roughness is shown in Table A.1.

Table A.1 — Estimation of the correlation between polishing grades and surface roughness

Polishing grade designation	Estimated R_q over a spatial bandwidth of 0,002 mm to 1,0 mm μm
P1	$\leq 0,008$
P2	$\leq 0,004$
P3	$\leq 0,002$
P4	$\leq 0,001$

Annex B (informative)

Relationship between surface texture and scattering characteristic of textured surfaces

It has been shown that there is an analytical expression relating surface texture to the angular distribution of light scattered by textured surfaces, see Reference [9]. Since scattered light can seriously compromise optical system performance and the measurement of surface texture or roughness tends to be easier than making scattered light measurements, it is useful to understand the relationship between surface roughness and scattered light.

It has also been shown experimentally that most polished surfaces scatter light according to a power law, see References [12] and [13]. Similarly a relationship between the two-dimensional power spectral density (PSD) of surface roughness or texture and the differential angular scatter has been obtained theoretically, see Reference [14]. Also the one-dimensional PSD, the raw data for which can be obtained with a one-dimensional profilometer, is simply related to the two-dimensional form for isotropic surfaces. It was shown that the one-dimensional PSD can be expressed as

$$\text{PSD} = \frac{A}{f^B}$$

where

- A is a constant, expressed in $\text{nm}^2 \times \text{mm}^{1-B}$;
- f is the spatial frequency of the surface roughness, in reciprocal millimeters (mm^{-1});
- B is the value of the exponent (or power) with which the PSD falls off with increasing spatial frequency. For most "real" surfaces, $1 < B < 3$.

This description of the PSD function is valid for a given range of spatial frequencies. The minimal spatial frequency is $1/D$, where D is the sampling length over which the sample was measured. The maximal spatial frequency is $1/C$, where C is the shortest lateral feature on the surface that the measuring instrument can resolve (C and D are expressed in millimetres).

Figure B.1 gives an example of three PSD functions for the case in which $B = 2$, and illustrates that the surface texture has smaller features as A is made smaller. These curves are for illustrative purposes only.

**Key**

X spatial frequency, in mm^{-1}

Y power spectral density, $\text{nm}^2 \times \text{mm}^{-1}$

Annex C (informative)

Examples of indication of surface texture requirements

Reference Number	Requirement	Example
C.1	Optical surface: — matt surface. Surface roughness: — a single, unilateral/upper specification limit; — $Rq \leq 2 \mu\text{m}$; — spatial bandwidth from 0,002 5 mm to 0,8 mm; — surface lay, no requirement.	
C.2	Optical surface: — matt surface. Surface roughness: — a single, unilateral/upper specification limit; — $Rq \leq 2 \mu\text{m}$; — upper limit of spatial bandwidth 0,8 mm; — surface lay, no requirement.	
C.3	Optical surface: — matt surface. Surface roughness: — bilateral specification limit; — upper specification limit $Rq = 2 \mu\text{m}$; — lower specification limit $Rq = 0,05 \mu\text{m}$; — upper limit of spatial bandwidth 5 mm; — surface lay, no requirement.	
C.4	Optical surface: — optically smooth surface; — polishing grade, no requirement; — numerical limit value of roughness, no requirement; — surface lay, no requirement.	

Reference Number	Requirement	Example
C.5	Optical surface: — optically smooth surface; — polishing grade 2; — < 80 microdefects per 10 mm linear scan; — numerical limit value of roughness, no requirement; — surface lay, no requirement.	
C.6	Optical surface: — optically smooth surface; — polishing grade 3; — < 16 microdefects per 10 mm linear scan. Surface roughness: — a single, unilateral/upper specification limit; — $Rq \leq 0,005 \mu\text{m}$; — spatial bandwidth from 0,002 mm to 1 mm; — surface lay, no requirement.	
C.7	Optical surface: — optically smooth surface; — polishing grade, no requirement. Surface roughness: — a single, unilateral/upper specification limit; — $Rq \leq 0,002 \mu\text{m}$; — upper limit of spatial bandwidth 1 mm; — surface lay, no requirement.	
C.8	Optical surface: — optically smooth surface; — polishing grade, no requirement. Surface roughness: — a single, unilateral/upper specification limit; — $Rq \leq 0,002 \mu\text{m}$; — spatial bandwidth from 0,002 mm to 1 mm; — surface lay, no requirement.
