Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 3.

Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this part of ISO 13909 may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

International Standard ISO 13909-3 was prepared by Technical Committee ISO/TC 27, *Solid mineral fuels*, Subcommittee SC 4, *Sampling*.

ISO 13909 cancels and replaces ISO 9411-1:1994, *Solid mineral fuels — Mechanical sampling from moving streams — Part 1: Coal* and ISO 9411-2:1993, *Solid mineral fuels — Mechanical sampling from moving streams — Part 2: Coke*, of which it constitutes a technical revision. It also supersedes the methods of mechanical sampling of coal and coke given in ISO 1988:1975, *Hard coal — Sampling* and ISO 2309:1980, *Coke — Sampling*.

ISO 13909 consists of the following parts, under the general title *Hard coal and coke — Mechanical sampling*:

- *Part 1: General introduction*
- *Part 2: Coal — Sampling from moving streams*
- *Part 3: Coal — Sampling from stationary lots*
- *Part 4: Coal — Preparation of test samples*
- *Part 5: Coke — Sampling from moving streams*
- *Part 6: Coke — Preparation of test samples*
- *Part 7: Methods for determining the precision of sampling, sample preparation and testing*
- *Part 8: Methods of testing for bias*

Annex A of this part of ISO 13909 is for information only.

Hard coal and coke — Mechanical sampling —

Part 3: Coal — Sampling from stationary lots

1 Scope

This part of ISO 13909 specifies procedures for the mechanical sampling of coal from stationary lots, for example from wagons, barges, ships and stockpiles. Procedures for sample preparation are given in ISO 13909-4.

This part is applicable to mechanical sampling from stationary coal lots, to obtain samples from which test samples for the determination of moisture, for general analysis including physical and chemical tests, and for size analysis can be prepared in accordance with the requirements and recommendations set out in ISO 13909-4.

In this part, the principles and procedures for designing a sampling scheme are given, together with typical examples of applications; in addition, practices for the execution of sampling in different sampling situations are described. The methods described are limited to those on which it is possible to conduct a test for bias.

2 Normative references

The following normative documents contain provisions which, through reference in this text, constitute provisions of this part of ISO 13909. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this part of ISO 13909 are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies. Members of ISO and IEC maintain registers of currently valid International Standards.

3 Terms and definitions

For the purposes of this part of ISO 13909, the terms and definitions given in ISO 13909-1 apply.

4 Establishing a sampling scheme

4.1 General

The general procedure for establishing a sampling scheme is as follows.

- a) Define the quality parameters to be determined and the types of samples required.
- b) Define the lot.
- c) Define or assume the precision required (see 4.4.1).
- d) Decide whether continuous or intermittent sampling is to be used (see 4.2).
- e) Determine the method of combining the increments into samples and the method of sample preparation (see ISO 13909-4).
- f) Determine or assume the variability of the coal (see 4.4.2 and, if relevant, 4.4.3) and the variance of preparation and testing (see 4.4.4). Methods for determining variability and variance of preparation and testing are given in ISO 13909-7.
- g) Establish the number of sub-lots and the number of increments per sub-lot required to attain the desired precision (see 4.4.5).
- h) Decide upon the sampling interval, in tonnes.
- i) Ascertain the nominal top size of coal for the purpose of determining the minimum mass of sample (see 4.5).

NOTE The nominal top size may initially be ascertained by consulting the consignment details, or by visual estimation, and may be verified, if necessary, by preliminary test work.

- j) Determine the minimum average increment mass (see 4.6).

4.2 Continuous and intermittent sampling

4.2.1 Continuous sampling

In continuous sampling, every sub-lot is sampled and the same minimum number of increments (see 4.4.5.2) is collected from each sub-lot. There are as many sample results for the lot as there are sub-lots. The mean result for the lot should be of the required precision but if it is desired to check that the required precision has been attained, it is possible to do this by using the procedures of replicate sampling described in ISO 13909-7.

4.2.2 Intermittent sampling

If coal of the same type is sampled regularly, it may be satisfactory to collect increments from some of the sub-lots but not from others. This is called intermittent sampling. The same minimum number of increments shall be taken from every sub-lot that is sampled (see 4.4.5.3). The sub-lots to be sampled shall be chosen at random, unless it can be demonstrated that no bias, for example as a result of time-dependent variance, is introduced by choosing sub-lots systematically. Such demonstration shall be repeated from time to time and at random intervals.

There are as many sample results per lot as there are sub-lots sampled, but because some sub-lots are not sampled, it is not possible to say whether the average of these results will have the required precision for the lot unless information about the variation between sub-lots is available. This can be obtained by following the procedure described in ISO 13909-7. If the variation between sub-lots is too large, it may be necessary to introduce continuous sampling to achieve the desired precision.

Any use of intermittent sampling shall be agreed between contracting parties and shall be recorded in the sampling report.

4.3 Design of the sampling scheme

4.3.1 Material to be sampled

The first stage in the design of the scheme is to identify the coal to be sampled. Samples may be required for technical evaluation, process control, quality control and for commercial reasons by both the producer and the customer. It is essential to ascertain exactly at what stage in the coal-handling process the sample is required and, as far as practicable, to design the scheme accordingly. In some instances, however, it may prove impracticable to obtain samples at the preferred points and, in such cases, a more practicable alternative is required.

4.3.2 Division of lots

A lot may be sampled as a whole or as a series of sub-lots, e.g. coal despatched or delivered over a period of time, a ship load, a train load, a wagon load, or coal produced in a certain period, e.g. a shift.

It may be necessary to divide a lot into a number of sub-lots in order to improve the precision of the results.

For lots sampled over long periods, it may be expedient to divide the lot into a series of sub-lots, obtaining a sample for each.

4.3.3 Precision of results

After the precision has been decided, the number of sub-lots and the minimum number of increments per sub-lot collected shall be determined as described in 4.4.5, and the average mass of the primary increments shall be determined as described in 4.6.

For single lots, the quality variation shall be assumed as the worst case (see 4.4.2 and 4.4.3). The precision of sampling achieved may be measured using the procedure of replicate sampling (see ISO 13909-7).

At the start of regular sampling of unknown coals, the worst-case quality variation shall be assumed, in accordance with 4.4.2, 4.4.3 and 4.4.4. When sampling is in operation, a check may be carried out to confirm that the desired precision has been achieved, using the procedures described in ISO 13909-7.

If any subsequent change in precision is required, the number of sub-lots and of increments shall be changed as determined in 4.4.5 and the precision attained shall be rechecked. The precision shall also be checked if there is any reason to suppose that the variability of the coal being sampled has increased. The number of increments determined in 4.4.5 applies to the precision of the result when the sampling errors are large relative to the testing errors, e.g. moisture. However, in some tests, the testing errors are themselves large. In this case, it may be necessary to form two or more test portions from the sample and use the mean of the determinations to give a better precision.

4.3.4 Bias of results

It is of particular importance in sampling to ensure, as far as possible, that the parameter to be measured is not altered by the sampling and sample preparation process or by subsequent storage prior to testing. This may require, in some circumstances, a limit on the minimum mass of primary increment (see 4.6).

When collecting samples for moisture determination from lots over an extended period, it may be necessary to limit the standing time of samples by dividing the lot into a number of sub-lots (see 4.4.5.1).

When a coal sampling scheme is implemented, it shall be checked for bias in accordance with the methods given in ISO 13909-8.

4.4 Precision of sampling

4.4.1 Precision and total variance

In all methods of sampling, sample preparation and analysis, errors are incurred and the experimental results obtained from such methods for any given parameter will deviate from the true value of that parameter. While the absolute deviation of a single result from the "true" value cannot be determined, it is possible to make an estimate of the precision of the experimental results. This is the closeness with which the results of a series of measurements made on the same coal agree among themselves, and the deviation of the mean of the results from an accepted reference value, i.e. the bias of the results (see ISO 13909-8).

It is possible to design a sampling scheme by which, in principle, an arbitrary level of precision can be achieved.

The required overall precision on a lot should be agreed between the parties concerned. In the absence of such agreement, a value of one tenth of the ash content may be assumed.

The theory of precision is given in ISO 13909-7. The following equation is derived:

$$P_L = 2\sqrt{\frac{V_I}{n} + \left(1 - \frac{u}{m}\right) \frac{V_m}{u} + V_{PT}} \quad (1)$$

where

P_L is the estimated overall precision of sampling, sample preparation and testing for the lot at a 95 % confidence level, expressed as percentage absolute;

V_I is the primary increment variance;

n is the number of increments per sub-lot;

u is the number of sub-lots actually sampled;

m is the number of sub-lots in the lot;

V_m is the sub-lot variance;

V_{PT} is the preparation and testing variance.

For continuous sampling, where $u = m$, equation (1) is simplified as follows:

$$P_L = 2\sqrt{\frac{V_I}{n} + \frac{V_{PT}}{m}} \quad (2)$$

If the quality of a coal of a type not previously sampled is required, then in order to devise a sampling scheme, assumptions have to be made about the variability (see 4.4.2 and 4.4.3). The precision actually achieved for a particular lot by the scheme devised can be measured by the procedures given in ISO 13909-7.

4.4.2 Primary increment variance

The primary increment variance, V_I , depends upon the type and nominal top size of coal, the degree of pre-treatment and mixing, the absolute value of the parameter to be determined and the mass of increment taken.

The number of increments required for the general-analysis sample and the moisture sample shall be calculated separately using the relevant values of increment variance and the desired precision. If a common sample is required, the number of increments required for that sample shall be the greater of the numbers calculated for the general analysis sample and the moisture sample respectively.

NOTE For many coals, the increment variance for ash is higher than that for moisture and hence, for the same precision, the number of increments required for the general analysis sample will be adequate for the moisture sample and for the common sample.

The value of the primary increment variance, V_i , required for the calculation of the precision using equation (1) can be obtained by either

- a) direct determination on the coal to be sampled using one of the methods described in ISO 13909-7, or
- b) assuming a value determined for a similar coal from a similar coal handling and sampling system.

If neither of these values is available, a value of $V_i = 20$ for ash content can be assumed initially and checked, after the sampling has been carried out, using one of the methods described in ISO 13909-7.

4.4.3 Sub-lot variance

The sub-lot variance, V_m , is influenced by the same factors as the primary increment variance but to a lesser degree.

If the sub-lot variance is known from previous experience, this may be used. If conditions permit, the sub-lot variance may be determined by the methods described in ISO 13909-7. In all other circumstances, a sub-lot variance of 5 shall be assumed initially.

4.4.4 Preparation and testing variance

The value of the preparation and testing variance, V_{PT} , required for the calculation of the precision using equation (1) can be obtained by either

- a) direct determination on the coal to be sampled using one of the methods described in ISO 13909-7, or
- b) assuming a value determined for a similar coal from a similar sample-preparation scheme.

If neither of these values is available, a value of 0,2 for ash content can be assumed initially and checked, after the preparation and testing has been carried out, using one of the methods described in ISO 13909-7.

4.4.5 Number of sub-lots and number of increments per sub-lot

4.4.5.1 General

The number of increments taken from a lot in order to achieve a particular precision is a function of the variability of the quality of the coal in the lot, irrespective of the mass of the lot. The lot may be sampled as a whole, resulting in one sample, or divided into a number of sub-lots resulting in a sample from each. Such division may be necessary in order to achieve the required precision, and the necessary number of sub-lots shall be calculated using the procedure given in 4.4.5.2 or 4.4.5.3, as appropriate.

Another important reason for dividing the lot is to maintain the integrity of the sample, i.e. to avoid bias after taking the increment, particularly in order to minimize loss of moisture due to standing. The need to do this is dependent on factors such as the time taken to collect samples, ambient temperature and humidity conditions, the ease of keeping the sample in sealed containers during collection and the particle size of the coal. It is recommended that, if moisture loss is suspected, a bias test be carried out to compare the quality of a reference sample immediately after extraction with the sample after standing for the normal time. If bias is found, the sample standing time should be reduced by collecting samples more frequently, i.e. increasing the number of sub-lots.

There may be other practical reasons for dividing the lot:

- a) for convenience when sampling over a long period;
- b) to keep sample masses manageable.

Establish the number of sub-lots and number of increments required per sub-lot in accordance with 4.4.5.2 or 4.4.5.3, as appropriate.

NOTE The formulae given in 4.4.5.2 and 4.4.5.3 will generally give an overestimate of the required number of increments. This is because they are based on the assumption that the quality of coal varies in a random manner. In addition, because a certain amount of preparation and testing is required when measuring the increment variance or the sub-lot variance, the preparation and testing errors are included more than once.

The designer of a sampling scheme should cater for the worst case anticipated and will then tend to use higher values for V_i and V_m than may actually occur when the scheme is in operation. On implementing a new sampling scheme, a check on the actual precision being achieved should be carried out using the methods described in ISO 13909-7. This may be necessary to achieve the required precision, in which case the number of sub-lots is calculated using the procedures given in 4.4.5.2 and 4.4.5.3.

4.4.5.2 Continuous sampling

Determine the minimum number of sub-lots required for practical reasons (see 4.4.5.1).

Estimate the number of increments in each sub-lot for a desired precision from the following equation [obtained by transposing equation (2)]:

$$n = \frac{4V_i}{mP_L^2 - 4V_{PT}} \quad (3)$$

A value of infinity or a negative number indicates that the errors of preparation and testing are such that the required precision cannot be achieved with this number of sub-lots. In such cases, or if n is impracticably large, increase the number of sub-lots by one of the following means.

- Choose a number corresponding to a convenient mass, recalculate n from equation (3) and repeat this process until the value of n is a practicable number.
- Decide on the maximum practicable number of increments per sub-lot, n_1 , and calculate m from the following equation.

$$m = \frac{4V_i + 4n_1V_{PT}}{n_1P_L^2} \quad (4)$$

Adjust m upwards, if necessary, to a convenient number and recalculate n .

Take n as 10 if the final calculated value is less than 10.

Examples of calculations for continuous sampling from stationary lots are given in annex A.

4.4.5.3 Intermittent sampling

Initially decide on the number of sub-lots, m , and the minimum number, u , required to be sampled for practical reasons (see 4.4.5.1).

Estimate the number of increments for a desired precision in a lot from the following equation [obtained by transposing equation (1)]:

$$n = \frac{4V_i}{uP_L^2 - 4\left(1 - \frac{u}{m}\right)V_m - 4V_{PT}} \quad (5)$$

A value of infinity or a negative number indicates that the errors of preparation and testing are such that the required precision cannot be achieved with this number of sub-lots. In such cases, or if n is impracticably large, increase the number of sub-lots by one of the following means.

- a) Choose a larger value for u , the number of sub-lots actually sampled, recalculate n and repeat this process until the value of n is a practicable number.
- b) Decide on the maximum practicable number of increments per sub-lot, n_1 , and calculate u from the following equation:

$$u = \frac{4m \left(\frac{V_l}{n_1} + V_m + V_{PT} \right)}{mP_L^2 + 4V_m} \quad (6)$$

Adjust m upwards, if necessary, to a convenient number and recalculate n from equation (5).

Take n as 10 if the final calculated value is less than 10.

Examples of calculations for intermittent sampling from stationary lots are given in annex A.

4.5 Minimum mass of sample

For most parameters, particularly size analysis and those that are particle-size related, the precision of the result is limited by the ability of the sample to represent all the particle sizes in the mass of coal being sampled.

The minimum mass of a sample is dependent on the nominal top size of the coal, the precision required for the parameter concerned and the relationship of that parameter to particle size. Some such relationship applies at all stages of preparation. The attainment of this mass will not, in itself, guarantee the required precision, because precision is also dependent on the number of increments in the sample and their variability (see 4.4.5).

Values for the minimum mass of samples for general analysis to reduce the variance due to the particulate nature of the coal to 0,01, corresponding to a precision of 0,2 % with regard to ash, are given in column 2 of Table 1 (see CSIRO report ^[1]). Column 3 of Table 1 gives the corresponding minimum masses of divided samples for total moisture analysis, which are approximately 20 % of the minimum masses for general analysis, subject to an absolute minimum of 0,65 kg.

The minimum mass of sample, m_S , for other desired levels of precision for determination of ash may be calculated from the following equation:

$$m_S = m_{S,0} \left(\frac{0,2}{P_R} \right)^2 \quad (7)$$

where

$m_{S,0}$ is the minimum mass of sample specified in Table 1 for a given nominal top size;

P_R is the required precision, with regard to ash, due to the particulate nature of the coal.

When a coal is regularly sampled under the same circumstances, the precision obtained for all the required quality parameters shall be checked (see ISO 13909-7) and the masses may be adjusted accordingly. However, the masses shall not be reduced below the minimum requirements laid down in the relevant analysis standards.

When preparing coal to produce samples for multiple use, account shall also be taken of the individual masses and size distribution of the test samples required for each test.

Table 1 — Minimum mass of sample for general analysis and determination of total moisture content

Nominal top size of coal mm	General-analysis samples and common samples kg	Samples for determina- tion of total moisture content kg
300	15 000	3 000
200	5 400	1 100
150	2 600	500
125	1 700	350
90	750	125
75	470	95
63	300	60
50	170	35
45	125	25
38	85	17
31,5	55	10
22,4	32	7
16,0	20	4
11,2	13	2,50
10	10	2
8,0	6	1,50
5,6	3	1,20
4,0	1,50	1,00
2,8	0,65	0,65
2,0	0,25	—
1,0	0,10	—

NOTE 1 The masses for the general analysis and common samples have been determined to reduce the variance due to the particulate nature of coal to 0,01, corresponding to a precision of 0,2 % ash.

NOTE 2 Extraction of the total-moisture sample from the common sample is described in ISO 13909-4.

4.6 Mass of primary increment

The mass, m_1 , in kilograms, of an increment taken by a mechanical auger (see clause 7) from a stationary lot of coal can be calculated from equation (8):

$$m_1 = \frac{\pi d^2 l \rho}{4} \quad (8)$$

where

d is the diameter of the auger tube, in metres;

l is the depth of penetration of the the auger, in metres;

ρ is the bulk density of the coal, in kilograms per m³.

The minimum average mass of primary increment to be collected, m'_1 , is calculated from equation (9):

$$m'_1 = \frac{m_S}{n} \quad (9)$$

where

m_S is the minimum mass of sample (see Table 1);

n is the minimum number of increments taken from the sub-lot (see 4.4.5).

With most mechanical augers, the mass of primary increment collected [see equations (8) and (9)] will greatly exceed that necessary to make up a sample of the required mass. In some cases, the primary increments are therefore divided, either as taken or after reduction, in order to avoid the mass of the sample becoming excessive.

When measuring primary increment variance (see ISO 13909-7:2001, clause 6) at preliminary stages in the design of the sampling scheme, use increment masses that are close to those expected to be taken by the system. After implementation of the sampling scheme, the precision of the result can be estimated and adjusted (see ISO 13909-7), by increasing or decreasing the number of increments in the sample, keeping the same increment mass.

4.7 Size analysis

Within the scope of this part of ISO 13909, the coals to be sampled will exhibit large differences in size, size range and size distribution. In addition, the parameters to be determined (percentage retained on a particular sieve, mean size, etc.) may differ from case to case. Furthermore, when sample division is applied, division errors shall be taken into account, whereas they are non-existent if sizing is performed without any preceding division.

Take these factors into account when applying the techniques for calculating numbers of increments for a particular precision (see 4.4.1 to 4.4.5). In the absence of any information on increment variance etc., initially take 25 increments per sample.

The precision for the particular parameter required shall then be checked and the number of increments adjusted according to the procedure described in ISO 13909-7.

Minimization of degradation of samples used for determination of size distribution is vital to reduce bias in the measured size distribution. To prevent particle degradation, it is essential to keep free-fall drops to a minimum. Trial tests should be made in accordance with the method given in ISO 13909-8 to determine the degree of degradation.

The minimum masses of sample for size analysis are given in Table 2. The masses have been calculated on the basis of the precision of the determination of oversize, i.e. the coal above the nominal top size. Precision for other size fractions will normally be better than this.

5 Methods of sampling from wagons, barges and ships

5.1 General

Sampling from stationary lots is carried out on a mass-basis only. The methods described in this clause are applicable to railway wagons, road wagons, shallow barges and ships up to a size such that full-depth sampling can be achieved. A sub-lot can be one or any number of wagons, an entire barge, several barges or one hold of a barge.

Table 2 — Minimum mass of sample for size analysis

Nominal top size of coal mm	Minimum mass for a precision of 1 % kg	Minimum mass for a precision of 2 % kg
300	54 000	13 500
200	16 000	4 000
150	6 750	1 700
125	4 000	1 000
90	1 500	400
75	950	250
63	500	125
50	280	70
45	200	50
38	130	30
31,5	65	15
22,4	25	6
16,0	8	2
11,2	3	0,70
10,0	2	0,50
8,0	1	0,25
5,6	0,50	0,25
4,0	0,25	0,25
2,8	0,25	0,25

5.2 Number of increments and sub-lots

5.2.1 General analysis and moisture samples

The number of sub-lots in the lot and the required number of increments in each sub-lot are calculated by the methods given in 4.4.5.

5.2.2 Common sample

Where a moisture sample is to be extracted from a common sample, the initial number of increments collected shall be that required for general analysis or moisture, whichever is the greater. Increase the mass of each increment or the number of increments if there will not be sufficient coal left for the general-analysis sample after the removal of the moisture sample in accordance with ISO 13909-4.

5.3 Taking the increments

Take increments using a mechanical auger or other suitable full-depth mechanical sampler; the use of an auger is preferred (see clause 7). Ensure that the sampler penetrates the full depth of coal and that a full column of coal is extracted, so that a representative increment is obtained. Large and hard pieces of coal or rock shall not be pushed aside deliberately when an increment is collected. Do not allow wet coal to adhere to the sampling equipment.

5.4 Distribution of increments

5.4.1 Wagons

5.4.1.1 Selection of wagons

If the number of increments required is less than the number of wagons in the sub-lot, take one increment from each of that number of wagons. When the number of increments required is greater than the number of wagons in the sub-lot, the number of increments taken from each wagon shall be determined by dividing the total number of increments by the number of wagons; if after this division there is a remainder of increments, these shall be distributed over the sub-lot. The selection of wagons may either be systematic (e.g. every third wagon), or random (see 5.4.3).

5.4.1.2 Position of increments within wagons

Vary the positions of the increments from wagon to wagon so that all parts are correctly represented. There are various methods of doing this and different schemes may be preferred for use with different designs or sizes of wagons.

For example, the coal surface in the wagon could be divided into numbered squares, each side about 1 m, the number of squares being dependent on the size of the wagon. If only a single increment is required from each wagon, systematic sampling can be used, i.e. taking increments from the numbered squares in rotation. In all other circumstances, random selection shall be used (see 5.4.4).

5.4.2 Barges

Although barges or even their holds are generally larger than wagons, the method of distribution of increments is, in principle, the same. Barges and/or barge-holds shall therefore be sampled using the procedures given in 5.3 and 5.4.1.2.

5.4.3 Ships

Subclauses 5.4.1 and 5.4.2 describe the use of a mechanical auger for sampling from the holds of wagons and of barges, i.e. those which have dimensions such that the conditions of sampling, especially to the full depth of the coal, are comparable to those prevailing when sampling from rail wagons.

Sampling of stationary coal in the holds of large barges and large ships is impracticable because of the difficulty of obtaining a full-depth representative sample. This difficulty increases with the size of the vessel and the normal practice with large vessels is to sample the coal from a moving stream (in accordance with ISO 13909-2) at port facilities during loading or unloading operations. Hence sampling from the holds of such vessels is excluded from this part of ISO 13909.

5.4.4 Random selection of increments

Identify all the possible sampling areas (wagons, barges, barge-holds or parts thereof) and number them. Select the areas to be sampled by one of the following methods:

- a) generate a random number for each increment required from a set corresponding to the total identified; or
- b) provide a set of numbered discs, one disc corresponding to each sampling area, and then proceed as follows.
 - 1) When selecting wagons, barges or barge-holds, place the discs in a bag and draw sufficient discs from the bag to coincide with the total number to be sampled. Attach the selected discs to a reference board and sample those wagons, barges or holds corresponding to the numbers on the selected discs.
 - 2) When selecting sampling areas within containers (wagons, barges or holds, see Figure 1), place the discs in a bag close to the sampling point and provide a diagram on a fixed board showing the locations of the areas across the surface of the coal. To sample the first selected container, draw sufficient discs from the bag to

coincide with the total number of increments to be taken from that container and take an increment from those areas corresponding to the numbers on the selected discs. Place these discs in a second bag after use. For the second container, follow the same procedure by drawing discs from those remaining in the first bag. Continue this process for subsequent containers until all the discs are used up and then swap the bags over so that discs are drawn from the second bag and placed in the first bag.

NOTE This procedure ensures that the order of the sampling areas from which increments are taken is always different.

6 Methods of sampling from stockpiles

Sample a stockpile when it is laid down or picked up by the method for sampling of moving streams described in ISO 13909-2. If it is not possible to sample the coal in this way, use the following method.

NOTE The sampling of a stockpile *in situ* usually presents problems in obtaining a representative sample and may be used only if it is not possible to sample the coal as a moving stream.

Stockpiles which are to be sampled from the surface shall be sufficiently compacted to safely bear the weight of sampling personnel and equipment.

Determine the number of sub-lots in accordance with 4.4.5 and calculate the mass of a sub-lot by dividing the mass of the lot by the number of sub-lots. Take increments using a mechanical auger (see clause 8). Ensure that a full column of coal is extracted, so that a representative increment is obtained, by using equipment that can penetrate to the bottom of the stockpile. Choose the positions of the boreholes so that all parts of the stockpile are represented by one of the following methods:

- divide the surface of the stockpile on a grid basis and take a core from each section of the grid; or
- carry out an initial ground survey and then take cores across the stockpile on the basis of sampling from equal volumes of coal.

7 Sampling equipment — mechanical auger

There are few commercially available, power-operated samplers which are suitable for mechanical sampling of coal. It is essential that any mechanical sampler used is capable of taking full-depth samples. One such sampler is the mechanical auger. Using an auger for sampling is preferred, but is impractical in some circumstances, for example, sampling of fuels of large top size.

An auger consists of a cylindrical steel tube containing an Archimedian screw (see Figure 2) which is mounted on a structure in such a way that it takes a vertical core from the full depth of the coal. The pitch of the screw and the

annular gap (the distance between the shaft and the inside of the tube) shall each be at least 3 times the nominal top size of the coal.

One particular design of Archimedian screw contains relatively few turns of the flight, leaving a space above the base of the auger which becomes filled with a column of coal during operation.

All mechanical sampling equipment shall be checked to ensure freedom from relevant bias in accordance with ISO 13909-8, by comparing samples obtained using the equipment with samples taken by the stopped-belt reference method.

8 Handling and storage of samples

Place the increments or divided increments as quickly as possible in sample containers and take appropriate precautions to minimize moisture losses during sampling. Seal the containers immediately after sampling is completed.

The increments or divided increments from each sub-lot shall be placed in a separate container or set of containers; if duplicate samples are required, a separate container or set of containers shall be provided for each duplicate sample respectively.

If common samples or moisture samples are required, the sample containers shall be impervious to water and vapour and have sufficient mechanical strength to ensure that the integrity of the sample will not be impaired during removal to the sample preparation site.

If general-analysis test samples are required, the sample containers for such samples shall provide adequate protection against contamination and loss of sample material, whereas they need not be impervious to water and vapour.

Moisture samples and common samples shall be kept in a cool, dry place during any storage, and the moisture shall be determined as quickly as possible after sample collection.

The sample in each sample container shall be fully and permanently identifiable. It is recommended that, for this purpose, the container be provided with two waterproof tags, each marked by means of waterproof ink with adequate identifying information, one tag being placed on the outside of the container and one being placed inside the container; if a plastic inner liner is used, the latter tag should be placed inside this liner.

When using a mechanical auger, unusually large increments are collected. Immediately after taking the increments, they should be prepared to manageable size using an on-line or off-line preparation facility. These facilities should be shown to be free from relevant bias.

9 Sample preparation

Sample preparation shall comply with the requirements of ISO 13909-4.

10 Minimization of bias

10.1 Causes of bias

The test results obtained from samples may be biased for a number of reasons. The causes of bias resulting from operation of the sampling equipment and the actions to be taken to minimize them are given in a) to c) below.

a) Improper operation

Inspection and/or measurement of the operating parameters shall be documented to verify compliance with the sampling plan, as well as the system specifications.

b) Improper maintenance

Maintenance of the sampler components shall be scheduled and documented by hours of use. Special attention shall be given to the maintenance of items that wear and/or need adjustments. For example, seals may wear causing material to be lost or drying to occur.

c) Improper cleaning

The mechanical sampling system shall be cleaned between lots to avoid sample contamination. Access to the interior of the system components is therefore essential.

10.2 Checking for precision and bias

The precision of sampling shall be checked using the methods described in ISO 13909-7 and, if necessary, adjustments made to the number of increments and/or sub-lots to achieve the specified precision. To this end, the scheme shall be designed so that increments can be processed separately and included alternately in at least two samples to produce replicate samples. It is not permitted to prepare duplicate samples from a number of increments already compounded.

The mechanical sampler shall be checked for bias by comparing the analysis of a sample taken by stopped-belt sampling and off-line preparation with that taken from the same coal by the mechanical system (see ISO 13909-8). This is of particular importance when moisture is to be determined on the crushed sample.

If preparation components are added to the sampler, they shall also be checked for bias.

11 Verification

Proper design shall be verified prior to installation and use. After installation, proper design shall be verified by conducting a bias test of the sampling scheme in accordance with ISO 13909-8.

Sampling plants should be rechecked for bias at predetermined intervals as part of a routine maintenance plan, to ensure that they remain free from bias.

NOTE The time intervals between these routine bias tests will depend on the throughput and type of fuel and on any modification/alteration of the system.
