Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

This document was prepared by Technical Committee ISO/TC 215, *Health informatics*, in collaboration with the European Committee for Standardization (CEN) Technical Committee CEN/TC 251, *Health informatics*, in accordance with the Agreement on technical cooperation between ISO and CEN (Vienna Agreement).

This first edition cancels and replaces ISO/TS 18530:2014, which has been technically revised.

The main changes compared to the previous edition are as follows:

- new definitions added;
- use case and UML diagrams updated;
- bibliography expanded.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at www.iso.org/members.html.

Introduction

The delivery of healthcare relies heavily on the ability to uniquely and accurately identify people when they attend for care, i.e. the Subject of Care (SoC), as well as, when they provide care, i.e. the Individual Provider.

Health informatics, supporting healthcare delivery, requires a clear specification to identify the SoC and the Individual Provider so that they are correctly associated with the health information contained within a healthcare application. This has led to the need to capture and share information across different systems and healthcare applications.

Data carriers, such as barcodes and Radio Frequency Identification (RFID), commonly referred to as Automatic Identification and Data Capture (AIDC), have amplified the importance of defining the identifier data structures for the SoC and Individual Provider to prevent ambiguity when information is being captured. AIDC provides a wide spectrum of solutions, in particular, regarding optical carriers (such as barcodes). Furthermore, the semantics of data carried is defined by a number of organizations (also named “issuing agencies”), some of them having commercial activities, others nation-wide missions, as well as, standard development organizations. This document focuses on the use of the GS1® System of Standards¹⁾ since a considerable majority of supplies in healthcare around the world are identified in accordance to this multisectorial and global system of standards. Interoperability is easier to secure once a single system of standards is used in the healthcare setting.

Interoperability, where information is shared and used by different information systems, requires a common SoC and Individual Provider identification semantic to ensure that shared information is consistent and unambiguous. The same SoC and Individual Provider are accurately identified, referenced and cross-referenced in each system. Effective data capture systems and information sharing is the key to improving the care of SoCs and delivery by Individual Providers in terms of conformance, accuracy and integrity of the health data.

In hospitals, a SoC (as in-patient) usually experiences a large number of care instances. Examples of these instances include: prescriptions and medicinal product administration, laboratory testing of SoC bio-samples and subsequent analysis and reporting. Each of these instances requires accurate reconciliation of the instance and delivery to the SoC. Healthcare providers (i.e. organizations that deliver healthcare to the SoC) have introduced AIDC technology based barcodes to help capture the SoC's identity, as well as, identification of other related items such as biology samples, so that manual key entry can be replaced by AIDC. In the complex hospital environment with many care instances, the need for uniqueness of identifications is generally recognized, since this avoids identification conflicts, overlaps, uncertainty and risks.

The use of AIDC in the context of chronic care reinforces the need for standards. The SoC in the chronic care instance is not always in the same fixed location where a single technology is available. AIDC can therefore be interoperable with a variety of technologies, solutions and devices. This will enable a continuum of care.

As out-patients, SoCs may be self-medicating. A SoC undergoing treatment for chronic conditions, in particular, should administer and record their medication according to a prescribed treatment plan. This treatment plan can be very prescriptive, on an as-needed basis, or be preventive in nature to avoid dangerous clinical outcomes.

There is also a need to manage and clinically monitor the treatment plan for the SoC for safety and stock purposes. AIDC enables capture of the SoC's identification, medicinal product, administration event, recording of relevant data about the medicinal product administered and other data such as batch number, expiration information and amount used. This should be done for in-patients as well as out-patients. This same data capture can be used to efficiently manage and replenish stock.

1) GS1 is a registered trademark. This information is given for the convenience of users of this document and does not constitute an endorsement by ISO.

Benefits from unique SoC Identification in AIDC can be documented from the following three examples:

- Patient, as well as, data can travel outside a provider's environment: Following a devastating tornado in Joplin, Missouri, USA, in 2011, 183 SoCs from St John's Hospital had to be swiftly evacuated to other regional hospitals. Under such “chaotic” conditions, a patient identifier that is truly unique would prevent replacing identification bands immediately for every SoC admitted to a different hospital.
- For regional referral laboratories, especially those performing blood bank testing: positively identifying SoCs and linking them to previous records, is essential for patient safety. Two different SoC with the same name, hospitalized at two different facilities using identical patient identification numbering schemes (perhaps because they use the same IT system), could lead to serious errors.
- A provider uses two identifiers for the management of care processes: the “patient identification” and the “case identification”. One provider organized the number banks for the two identifiers in such a way, that data collision was excluded. After years of use of that solution, number banks started overlapping without anyone noticing, until two SoCs were having the same numbers, one of “patient identification”, the other for “care identification”. A mismatch with serious incident occurred.

Health informatics — Automatic identification and data capture marking and labelling — Subject of care and individual provider identification

1 Scope

This document outlines the standards needed to identify and label the Subject of Care (SoC) and the Individual Provider on objects such as identification (wrist) bands, identification tags or other objects, to enable automatic data capture using data carriers in the care delivery process.

It provides for a unique SoC identification that can be used for other purposes, such as recording the identity of the SoC in individual health records.

This document serves as a reference for any organization which plans to implement or improve Automatic Identification and Data Capture (AIDC) in their delivery of care process. It is based on the use of the GS1® system of standards. Other solutions, such as using other identification systems (for example, systems based on ISBT 128), are possible but not addressed by this document.

This document describes good practices to reduce/avoid variation and workarounds which challenge the efficiency of AIDC at the point of care and compromise patient safety^{[5][6]}.

This document specifies how to manage identifiers in the AIDC process, and completes the information found in ISO/TS 22220 and ISO/TS 27527.

2 Normative references

There are no normative references in this document.

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <http://www.electropedia.org/>

3.1

application identifier

AI

GS1® prefix that defines the meaning and purpose of the data element that follows, as defined in ISO/IEC 15418 and GS1® General Specifications

[SOURCE: ISO/IEC 19762:2016, 01.01.82]

3.2

automatic identification and data capture

AIDC

methods or technologies for automatically identifying objects, collecting data about them, and entering that data directly into computer systems, eliminating manual entry

Note 1 to entry: The methods or technologies typically considered as part of AIDC include barcodes, which can be linear or 2-dimensional symbols, and Radio Frequency Identification (RFID) tags/chips.

3.3

data capture

deliberate action that results in the registration of a record into a record keeping system

3.4

care unit

ward

subdivision of an organization where the *subject of care* (3.15) receives the care they need during their stay

3.5

global service relation number²⁾

GSRN

identification key to identify the relationship between an organization offering services and the recipient or provider of services

Note 1 to entry: GSRN are encoded on data carriers with an Application Identifier 8018 for the recipient of a service (Subject of Care) and with an Application Identifier 8017 for the provider of a service (Individual Provider).

3.6

healthcare provider

organization or facility that delivers healthcare to subjects of care

3.7

integrating the healthcare enterprise

IHE®³⁾

initiative by healthcare professionals and industry to improve the way computer systems in healthcare share information

Note 1 to entry: IHE® promotes the coordinated use of established standards to address specific clinical need in support of optimal patient care.

Note 2 to entry: Systems developed in accordance with IHE® communicate with one another better, are easier to implement, and enable care providers to use information more effectively.

3.8

individual provider

person who provides or is a potential provider of a health care service

Note 1 to entry: An individual provider is an individual person and is not considered to be a group of providers.

Note 2 to entry: Not all health care providers are recognized by professional bodies. It is for this reason that 'health care professional' has not been used to describe them. All health care professionals are providers, but not all providers are health care professionals.

3.9

individual provider identification

unique number or code issued for the purpose of identifying an individual provider

3.10

information system

organized collection of hardware, software, supplies, policies, procedures and people that stores, processes and provides access to information

2) GSRN is the GS1® identifier for service relations and is supplied by the GS1® System. This information is given for the convenience of users of this document and does not constitute an endorsement by ISO of the service relation identifier named. Equivalent products may be used if they can be shown to lead to the same results.

3) IHE is the registered trademark of the Healthcare Information Management Systems Society. This information is given for the convenience of users of this document and does not constitute an endorsement by ISO.

3.11**machine readable code**

code, readable by a machine, which contains information used to establish a relationship between a physical object such as a medical product package and data sources such as medical, production, logistical and/or reimbursement coding systems

3.12**record**

recorded information, in any form, including data in computer systems, created or received and maintained by an organization or person in the transaction of business or the conduct of affairs and kept as evidence of such activity

3.13**registration**

act of giving a record a unique identity in a record keeping system

3.14**service relation instance number****SRIN**

attribute to a *global service relation number* (3.5) to identify an instance within a care process

EXAMPLE An identification band, an order sheet, a test-tube, etc.

3.15**subject of care****SoC**

person seeking to receive, receiving or having received health care

4 GS1® specifications and ISO deliverables

In this document, automatic identification and data capture (AIDC) refers to selected data carriers which are widely used across many industries, jurisdictions and which are already based on and specified in ISO deliverables. The benefit of this approach is to use the already widely available applications and devices for encoding and reading the different types of data carriers. It should, however, be noted that certain types of data carriers such as data matrix may only be read by image-based scanners.

AIDC solutions should be in accordance with GS1® general specifications, which in-turn are based on ISO deliverables. If the recommendation is followed, then information contained in the data carriers shall be structured and standardized according to the GS1® semantics. The identification key (global service relation number, GSRN) is the identifier for service relations (such as SoC and Individual Providers) and is supplied by the GS1® System of Standards.

5 Data structures and semantics**5.1 Application identifiers**

The GS1® item identification system and related encoding standard are complemented by the GS1® maintained application identifiers, hereafter referred to as “GS1® Application Identifiers” or “GS1® AIs”. This document comprises two principal elements that are the key to any encoding system: the data content and the data carrier.

The use of GS1® AIs is subject to the rules established by GS1®.

GS1® maintains a list of over 200 AIs which support various processes with automatic identification and data capture.

5.2 Global service relation number (GSRN)

The GSRN is the GS1® Identification Key used to identify the relationship between an organization offering services and the recipient or provider of services. The key comprises of a GS1® Company Prefix, Service Reference and Check Digit, with an 18 numeric digits fix length.

Two different AIs are used to distinguish SoC from individual provider as illustrated in [Figure 1](#).

Figure 1 — Global service relation number (GSRN)

5.3 Service relation instance number (SRIN)

The SRIN is an attribute to the GSRN which allows distinguishing different encounters during the same episode, or the reuse of the same GSRN in different episodes. SRIN is a 10 numeric digits variable length field. AI 8019 shall only be used in conjunction with AI 8017 or 8018; [Figure 2](#) illustrates the combination for a SoC.

Figure 2 — Service relation instance number (SRIN)

For the purpose of this document, for conformance with ISBT 128, the SRIN shall be used as a fixed length string with the first two digits (NN) reserved for the ISBT 128 location code (Table RT018); the selection of the remaining eight (8) digits is left to the discretion of the user and may be incremental.

6 SoC and Individual Provider identification as a recognized priority

6.1 General

The World Health Organization (WHO) and the Joint Commission International (JCI) have developed a list of priority solutions to enhance patient (meaning SoC) safety. Among the list of solutions WHO and JCI recommended is the use of AIDC technology (when the technical framework permits). Among the "Nine patient safety solutions"^[1] given by WHO, the second solution^[2] addresses patient (SoC) identification and the use of "barcodes" to reduce the risk of identification errors. Other solutions (communication during patient hand-over; performance of correct procedures at correct body site; assuring medication accuracy at transitions in care) require security of a patient's (SoC's) identification.

[Annex A](#) illustrates how SoC and Individual Provider identification should be enabled for different types of healthcare care use cases. If used, the [Annex A](#) explains the type of care and how AIDC can be implemented as a good practice in different use cases. The following use cases (UC) are included:

- UC 01 to 04 covers the typical overall SoC flow through a hospital (see [Figure A.1](#));
- UC 05 to 11 describes specific care instances that might arise within a hospital environment (see [Figure A.2](#));
- UC 12 to 19 looks at machine readable coding in complex point of care environments (see [Figures A.3 and A.4](#));
- UC 20 to 24 looks at machine readable coding in the blood transfusion processes (see [Figures A.4 and A.5](#));
- UC 25 to 27 describes machine readable coding for chronic outpatients (see [Figure A.6](#));
- UC 28 to 30 examines the need to integrate nationwide SoC and Individual Provider identification (see [Figure A.7](#)).

The textual presentation of the use cases is completed with UML diagrams where, in particular, data capture is positioned; instructions are included in the “good practice” section.

In each of the use cases, there is requirement to provide unambiguous data qualifiers to distinguish between the SoC, the Individual Provider and the product for data capture. Without qualifiers, it is impossible to guarantee that the captured information (or data) is what was intended. There is also the possibility of duplication of identity. This is avoided by using a standardized globally unique identification.

6.2 Supported processes

[Annex A](#) provides examples of a series of processes that are supported by capturing SoC identifier, SRIN and Individual Provider identification. [Table 1](#) (based on the examples found in [Annex A](#)) provides an overview so that implementers can evaluate their needs and the appropriate solution to adopt.

Table 1 — Overview of supported processes

Usage Requirements	SoC identifier	SRIN	Individual Provider Identification
SoC and Individual Provider Identification as a recognized priority	X		X
Machine readable coding for clinical purpose (point of care)	X	X	X
Machine readable coding in complex point of care environments	X	X	X
Machine readable coding to avoid workarounds	X	X	X
Machine readable coding in the blood transfusion processes	X	X	X
Machine readable coding for chronic outpatient	X	X	X
Machine readable coding by integrating nationwide SoC identification	X	X	X

7 The purpose of globally unique identification

7.1 SoC identification and data processing

When GSRN is used in data processing, solutions have been developed by IHE® International as Master Patient Indexes (MPI), which secure uniqueness of the identification in a defined environment and associates defined demographics to a SoC identifier. MPI should be interconnected by using IHE® tools so that heterogenic identifications are linked together by using the associated demographics. The use of GSRN, as described in this document, does not impact data processing and the use of IHE® tools, since IHE's ®MPI are conceived to address situations where SoC are identified with **any** identifier.

GSRN are fixed length 18 digits numeric keys according GS1® General Specifications^[8]. In a GS1® DataMatrix, the SoC GSRN shall be headed by a GS1® AI 8018.

7.2 Implementation challenges

Modern CIS require the use of a SoC identifier and an Individual Provider identification so that processes can be captured with scanning technologies. Some implementation challenges have been noticed, such as the following:

- Acceptance by Individual Provider: To prevent AIDC technologies consuming the Individual Provider's time, it is important to associate these professionals to the implementation steps, including working ergonomic, graphic user interfaces, etc. A benefit of AIDC should be the reduction of administrative work (manual key entries in the nursing files, reordering of consumed products, etc.). Furthermore, it is important that any implementation requires scanning **prior** care processes, so that alerts are issued to prevent errors (scanning after care process would be too late to avoid error). Some processes require even two data captures: one prior to the care process (checking adequacy) and one after the care process (confirming end of process). An example for this double step is the administration of cytostatics^[3].
- CIS data-field limitations: the length of the Individual Provider identification and the SoC identifier, when using GSRN, is 18 numeric digits. The optional SRIN for a SoC is a numeric field of up to 10 digits. The CIS is frequently not able to work with such data fields. It is important that healthcare providers and vendors collaborate to understand the value and the flexibility of the solution so that CIS support evolutions for the benefit of efficiencies (reducing manual key entries for documentation processes) and patient safety (combating workarounds^{[5],[6]}, checks ahead of care processes, etc.). It is recommended to add appropriate reference in the future call for tender. As an intermediary (temporary) solution, a middleware (e.g. in the form a web service) can be developed or found on the market, to link SoC's GSRN, SRIN, as well as, Individual Provider identification (GSRN) to the existing CIS.

7.3 Symbol placement on identification bands

Barcoding technologies have addressed SoC identifiers on identification bands for years. Therefore, the following experiences should be leveraged:

- Linear/2-dimensional barcodes: linear barcodes are frequently too long to be easily read on identification bands (i.e. because of the curve of the band around the limb). Therefore, DataMatrix is recommended for carrying GSRN and when possible SRIN.
- Two data carriers on the identification band may be necessary for a transition period, since some software may not be able to handle long identification keys. It is a common situation which adds to the potential risk that the two identifiers (the long and the short) do not point to the same SoC. Therefore, such a situation should only be considered for limited periods of time.
- Ease of finding the data carrier: industry experience demonstrates that (because of the limb's curve) the identification band is not always in the same position, thus the data carrier not always visible. The same DataMatrix should be printed optimally 4 times along the identification band. Scanner devices shall be programmed not to read the same DataMatrix more than once. The presence of

SRIN as an attribute to GSRN provides the benefit that the scanner analyses if the DataMatrix is the same or not. Results of reading more than once the GSRN and SRIN shall be rejected by the scanner.

- Ease of reading the data carrier: industry experience demonstrates that the DataMatrix should always be printed in the middle of the identification band or label (not on its side). This avoids truncations and overlaps, which burden Individual Providers and thus could influence their process conformance.
- In neonatology, it is usual to affix more than one identification band on young babies (e.g. one on the arm, one on the leg). The use of GSRN and SRIN is compatible with this situation, and the CIS should be able to validate that two SRIN are used on identification bands at the same time, for such particular situations.

7.4 Individual Provider identification

Individual Providers do not carry the same type of identification bands as SoC. Individual Provider identification is frequently stored on cards such as identity cards, which allow computer login, room access, etc. Individual Provider identification may be carried in RFID chips, which are defined by software vendors and the solutions implemented by the healthcare provider.

Individual Provider identification is used, not only in the care processes as described in this document but can also be used for rule management (allowing access to information relating to Individual Provider qualifications, functions, etc.), for patient record access and other functionalities at the healthcare provider's discretion.

Individual Provider identification should be defined by the healthcare provider for its staff and the Individual Providers licensed to work in its premises. The use of GSRN should allow larger organizations using the same Individual Provider identification with structured decentralized identification management, by avoiding overlaps and identification errors.

GSRN are fixed length 18 digits numeric keys according to GS1® General Specifications. In a data carrier such as GS1® DataMatrix, the Individual Provider GSRN shall be headed by a GS1® Application Identifier 8017.

Annex A **(informative)**

Examples of use cases (UC)

A.1 The typical hospital care process (UC 01 to 04)

A.1.1 General

The use of machine-readable coding enhances the hospital care delivery at different stages of the care cycle. Typical hospital use-cases reflect interaction between the SoC and Individual Providers along a care pathway. This is simplified, at high level and generic. In reality, each care process may differ from hospital to hospital.

The typical hospital stages are the following:

- a) Admissions: the SoC presents at the hospital;
- b) Care unit: when the SoC is admitted to the care unit or ward;
- c) Surgical: when the SoC undergoes a clinical procedure;
- d) Discharge: after the procedure and recovery the SoC is discharged back to the community.

Each of these stages is concerned with the movement of the patient through the care pathway and assuring the identity of the SoC.

A.1.2 Use cases

A.1.2.1 Admission process (UC 01)

The SoC arrives at the admissions department. The SoC provides his/her identity using an identification card or by other means. Other documents such as the referral letter and related insurance details may also be provided. The Admissions Clerk verifies the SoC's identity, the reason for admission as detailed in the referral letter and, registers the SoC for admission. The SoC is issued an identification band and a series of adhesive labels, each detailing the name and appropriate demographics, as well as, the SoC Identifier (GSRN). The identification band is attached to the patient and the labels are placed in a record folder which the SoC brings to the care unit. Alternatively, stickers should be printed "on demand" at point of care

A.1.2.2 At the care unit (UC 02)

The SoC is welcomed, brought to the ward, and prepared for bed; identification of bed as location is captured. Clinical information, i.e. temperature, blood pressure etc., is collected and recorded. Bio samples are collected in a sample tube and sent to the hospital laboratory.

A.1.2.3 Surgical operation (UC 03)

The SoC is prepared for surgical operation. A medicinal product is administered to the SoC and the SoC is brought to the preparation room where anaesthetics are injected. The SoC is wheeled into the operating theatre. After the operation is completed, the SoC is brought to the recovery room. When the SoC is ready, the SoC is returned to the ward.

A.1.2.4 Discharge (UC 04)

Once the SoC has recovered, the care pathway is complete. The SoC is transferred to a rehabilitation clinic. A hospital discharge letter is prepared and sent ahead of the arrival SoC at the rehabilitation clinic.

A.1.3 UC 01 to UC 04 process flow

Figure A.1 — UC 01 to 04 process flow

A.1.4 Good practice

A.1.4.1 General

Applying AIDC to the above processes, good practice would consist of the following in each of the stages:

A.1.4.2 Admission process (UC 01)

Once the identity of the SoC is confirmed (ISO/TS 22220 providing guidance for this process), the identification band(s) should be issued detailing in human readable form the SoC's name, gender and date of birth. GS1® DataMatrix symbols should be printed at least 4 times on the same identification band (See 8.3). The GS1® DataMatrix contains the SoC identifier (Global Service Relationship Number, GSRN), as well as, the attribute Service Instance Number (SRIN). At the same time, adhesive labels are printed containing the same human readable information as the identification band including a GS1® DataMatrix with the same GSRN, but each SRIN shall be different.

A.1.4.3 At the care unit (UC 02)

The Individual Provider at the care unit scans the SoC identification band to register the SoC in the ward and to access the SoC's individual health record. Based on orders / prescriptions, bio-samples are taken, and each sample tube should be labelled with the pre-printed labels issued during admissions.

Alternatively, the same labels should be printed on demand at the point of care. Each label shall contain a GS1® DataMatrix with the GSRN and a different SRIN.

When taking the bio-samples and before shipment of the samples to the laboratory, the GSRN from the identification band should be linked to the GSRN and SRIN stuck on the label sample tube(s). Results of the sample analysis are then used to update the SoC's individual health record.

A.1.4.4 Handover in the preparation room (UC 03)

AIDC should be used to transfer the patient to the preparation room and trigger the setup of the operation. This should be accomplished using the GSRN and SRIN in the identification band. The SoC's individual health record is updated. Pre-operative bio-samples identified with the GSRN and SRIN are taken, linked to the SoC's GSRN and sent to the laboratory for analysis. Analysis identified with the GSRN and SRIN should be reported and linked to the SoC's individual health record.

A.1.4.5 Operating room (UC 03)

The SoC is transferred to the Operating Room. The GSRN should be scanned on the SoC identification band to register the transfer. All Operating Room activities should be linked to the SoC until the end of the operation and should be recorded in SoC's individual health record. The SoC is transferred to the recovery room. The transfer to the recovery room should be registered by scanning the GSRN. Finally, the SoC is returned to the care unit and should be registered by scanning the GSRN.

A.1.4.6 Discharge (UC 04)

On discharge, a discharge letter is printed which should include the SoC's GSRN and a different SRIN in a GS1® DataMatrix. The SoC leaves the hospital.

A.1.4.7 Conclusions

In conclusion, the use of machine-readable coding enhances the verification processes for the SoC care pathway. The risk of error is reduced by assuring the identity of the SoC at each step. Manual data entry can be reduced significantly eliminating key entry errors and improving efficiency. The overall outcome is mitigating risk of administration errors at the point of care.

A.2 Specific care instances that might arise within a hospital environment (UC 05 to 11)

A.2.1 General

There are many circumstances where SoC identification has to be captured in relation with care processes. Some typical situations are grouped in this section to illustrate the diversity of the context and the value of machine-readable codes.

A.2.2 Use cases

A.2.2.1 General

The following use case instances illustrate typical situations in the care processes. The care instances, which do not correspond to a logical sequence, highlight the added value gained by using internationally adopted identification standards and AIDC. Added value consists of more efficiency in the use of human resources and safer care to the SoC.

The examples in this use case illustrate common instances of care delivered to a SoC:

- a) Medication is prepared for a SoC and administered to the SoC in the ward, (Use cases 06 and 07);
- b) Centrally prepared SoC medication and administered to the SoC in the ward, (Use Cases 08 and 09);
- c) SoC Bio-sample taken for laboratory analysis (Use Case 10);
- d) SoC transferred from one Provider (hospital) to another Provider (hospital), (Use Case 11).

A.2.2.2 Machine readable codes for care instances at the point of care (UC 05)

Care instances a) and b) illustrate machine readable codes validating the administration of the right medicinal product to the right SoC, i.e. the right dose, at the right time, in the right form, through the right route of administration and by the appropriate Individual Provider. This is also referred to as “full match”.

In the care instances a) and b), the machine-readable codes are used for validating the administration of the right medicinal product to the right SoC, i.e. the right dose, at the right time, in the right form, through the right route of administration and by the appropriate Individual Provider (full match).

A.2.2.3 Medication preparation (UC 06) and medication administration in the ward (UC 07)

Based on the electronic prescription, the Individual Provider in the ward selects and scans the data carriers printed by the medicinal product manufacturer for each SoC separately and places the medicinal product packages in an individual drawer identified with a label and with a dedicated space for each time of the day.

The Individual Provider scans the GSRN on the identification band and the GSRN and SRIN on the label on the drawer to check the selection of the correct drawer for this SoC (this ensures the right drawer for the right SoC). Each medicinal product package should be scanned before administering to SoC. If full match does not occur, an alert is to be issued to prevent potential medication error (e.g. wrong medicinal product, dosage, route of administration or time). When full match occurs, medication administration is captured and documented in the SoC's individual health record.

A.2.2.4 Centrally prepared individual medication (UC 08) and medication administration in the ward (UC 09)

Based on the electronic prescription, the hospital pharmacist selects and scans the data carriers printed by the medicinal product manufacturer for the SoC's prescription and places it in individual bags. Each bag is identified with the SoC's GSRN and a SRIN. A link between bag and medicinal product(s) is established by scanning each of the respective identifiers. The bags are delivered to the ward.

The Individual Provider scans the GSRN on the SoC's identification band and the GSRN and SRIN on the bag's label to check the appropriate bag for the SoC (this ensures the right bag for the right SoC). Each medicinal product package should be scanned before administering to the SoC. If full match does not occur, an alert shall be issued to prevent potential medication error (e.g. wrong medicinal product, dosage, route of administration or time). When full match does occur, medicinal product administration is captured and documented in the SoC's individual health record.

A.2.2.5 Bio-sample taken from SoC for analysis (UC 10)

An order having been placed for a bio sample by an Individual Provider; the Individual Provider prints a label containing a GSRN and SRIN and attaches it to the sample tube. The bio-sample is taken from the SoC. The SoC identification band and sample tube are scanned to link them to the order which had requested the analysis.

A.2.2.6 SoC transferred from one Individual Provider to another Individual Provider (UC 11)

This is the situation when a SoC is transferred from one Provider to another Provider; the second captures the SoC's identification from his/her identification band, recognizes the SoC and links his/her previous identification to the local individual health record and GSRN.

EXAMPLE A badly burned SoC arrives in emergency at a Provider. Immediate care is provided, and the admission process is completed. The SoC is issued with an identification band "1" containing a GSRN. Due to the SoC condition and needs, the SoC has to be transferred to a specialized burns unit Provider. The specialized provider is informed of the SoC identification, the SoC's condition and the care received before transfer. When the SoC arrives at the specialist Provider, the SoC's identification band "1" is read to confirm the correct SoC and a new identification band is issued by the specialist Provider.

A.2.3 UC 05 to 11 process flow

Figure A.2 — UC 05 to 11 process flow

A.2.4 Good practice

A.2.4.1 General

Focusing on AIDC processes, good practice consists in the following.

A.2.4.2 Medication preparation process (UC 06 and UC 08)

Regardless of whether it is preparation in the ward or in central pharmacy at hospital pharmacy, the electronic prescription guides the Individual Provider in the choice of the right medicinal product, which should be verified by scanning the product unique identifier (GS1® Global Trade Item Number

– GTIN®). The medicinal product is linked to the SoC by scanning the GTIN® and GSRN/SRIN on the drawer and placing the medicinal product package in the drawer/bag.

A.2.4.3 Medication administration in the ward (UC 07 and UC 09)

The Individual Provider matches the GSRN in the SoC's identification band to the individualized drawer or bag. The GSRN are matched and SRIN differ from each other. This process documents that the right SoC and the right drawer or bag are selected. Before administering medicinal product(s) to the SoC, the Individual Provider scans every medicinal product primary package so that appropriateness is verified by the IT system toward the electronic prescription (the right medicinal product and dosage, at the right time, through the right route of administration). Once the match is positive, medication is given and recorded in the individual health record.

A.2.4.4 Bio-sample taken from SoC for analysis (UC 10)

Laboratory order (electronic prescription) requires an Individual Provider to take a bio-sample from a SoC for analysis purpose. The Individual Provider issues a label for the sample tube including GSRN and SRIN. By taking a bio-sample from the SoC, the identification band and test tube are matched by scanning from Individual Provider so that the IT system can verify the GSRN being the same, and the SRIN being different. This done, GSRN and sample tube's SRIN are linked to the electronic prescription (laboratory order).

A.2.4.5 SoC transferred from one Provider to another Provider (UC 11)

This Use Case illustrates how first GSRN shall be linked to second GSRN when the SoC does physically transfer from one Provider to another, and accordingly is allocated a new GSRN by the second clinical information or patient administration system.

A.3 Machine readable coding in complex point of care environments (UC 12 to 19)

A.3.1 General

Complex point of care environments such as a (paediatric) intensive care, or an operating room (OR) requires particular attention. In such situations, there is a need for appropriate solutions to ensure consistent data capture. For example, the small size of the child's arm affects the size of the identification band and, therefore, the size and placement of the data carrier. Sometimes, there is the need to remove the identification band and to replace it at later stage.

A.3.2 Use cases

A.3.2.1 General

The use cases describe what occurs when using AIDC and linking to the interfaces with medical devices used to monitor the SoC's vital signs, point of care testing results, and electronic anaesthesia record (Anaesthesia Workstation). It also describes the case when an Individual Provider has to search and cross-match labile blood products or tissues from outside the operating room.

A.3.2.2 SoC arrives at the OR reception area (UC 12)

The SoC's identity is matched to all applicable OR documentation, including the surgical flow sheet used to record the events during surgery. This is done by matching the GSRN to the operating room documents and records.

A.3.2.3 SoC entry into the operating room (OR) (UC 13)

SoC's identification band is scanned. At this point of time, all the IT systems in the OR are linked to this SoC.

A.3.2.4 “Time out” period (before the patient is draped) (UC 14)

The verification process uses AIDC to alert the Individual Provider and block further processes, if there is an error. Verification is based on checking the following:

- SoC identification;
- surgical procedure;
- surgical site;
- ordered medicinal product(s) (e.g. prophylactic antibiotics);
- blood products/tissues.

A.3.2.5 Anaesthesia is administered before SoC is draped (UC 15)

At this point, the identification band (“primary identification band”) may be removed to facilitate access to the SoC’s blood vessels, as in the case of small infants. A new identification band (“secondary identification band”) is immediately printed (by scanning the primary identification band) and attached to the OR computer/monitor for identification purposes while the patient is draped. The “primary identification band” is de-activated (archived) and replaced by producing the “secondary identification band”.

A.3.2.6 Searching labile product during operation (UC 16 and UC 16a)

If/when a labile product is needed during the procedure, the Individual Provider will take the “secondary identification band” to the refrigerator where a cross-match is processed. When complete, the Individual Provider returns with the “secondary identification band” and the matched products. The “secondary identification band” is immediately placed back on the OR computer/monitor.

A.3.2.7 SoC is draped and surgery is performed (UC 17 and UC 17a)

AIDC is used during surgery to scan and verify each medicinal product and blood product to check their appropriateness and to record their use during surgery. Some medicinal products (prophylactic antibiotics, steroids) are pre-ordered and issued by the pharmacy to the OR for the specific SoC. These should be electronically matched to the SoC prior to administration to verify and record the right SoC to right medicinal product, dose, batch/lot number and expiry date. Electronic anaesthesia records enable all SoC data (monitored vital signs, all medicinal products administered) to be electronically recorded. When using AIDC, it prevents the use of the wrong medicinal product and, at the same time, records the administration and usage in the SoC’s operation record since all IT systems in the OR are locked to the SoC. As all events in the OR are linked to the particular SoC, there may be no need to repeatedly scan the SoC’s identification.

A.3.2.8 The SoC identification is rechecked before leaving the OR (UC 18)

If the “primary identification band” remains attached to the SoC during the procedure, it is scanned to record the end of operation. If the “primary identification band” had been removed, the “secondary identification band” is now attached to the SoC and is scanned to record the end of the operation.

A.3.3 UC 12 to 18 process flow

Figure A.3 — UC 12 to 18 process flow

A.3.4 Good practice

A.3.4.1 General

Focusing on AIDC processes, good practice consists in the following.

A.3.4.2 SoC arrives at the OR reception area (UC 12)

SoC identification is captured so that the computerized support systems are set up for the individual SoC. The GSRN is scanned to identify the SOC. Individual Provider Identification is captured by reading her/his identification band.

A.3.4.3 SoC entry into the OR (UC 13)

SoC identification band and Individual Provider Identification are scanned to record the SoC entering the OR.

A.3.4.4 Anaesthesia is administered before SoC is draped (UC 14)

If it is necessary, i.e. when a primary identification band is removed to allow access to the SoC, then the process to issue the “secondary identification band” should use the previous (“primary”) band. The primary band is scanned, and the new secondary identification band is generated which includes the same GSRN and a new SRIN. This allows AIDC on the new secondary identification band to be distinguished from AIDC on previous primary identification band, but at the same time maintains a process link. In such cases, the (new) identification band should be affixed in a distinct, pre-defined place so that AIDC is processed with no confusion risk.

A.3.4.5 “Time out” period (before the patient is draped) (UC 15)

Prior to starting the surgery, inventory should be checked to ensure that all requirements and items needed are available. That check uses AIDC to record the data from the SoC’s identification band, medicinal products, medical devices, blood products, etc.

A.3.4.6 Searching labile product during operation (UC 16 and UC 16a)

If/when a labile product is needed during the procedure, the Individual Provider takes the “secondary identification band” to the refrigerator where a cross-match is processed. When complete, the Individual Provider returns with the “secondary identification band” and the matched products. The “secondary identification band” is placed back on the OR computer/monitor.

A.3.4.7 SoC is draped and surgery is performed (UC 17 and UC 17a)

During the surgical process, because the GSRN has already been scanned, registered and locked in the systems, medicinal products, anaesthetics, devices scanned prior to administration or use for SoC are linked to the GSRN. This facilitates continuous recording of events relating to the SoC in the OR linked by the GSRN. It allows for additional alerts as the SoC’s surgical process evolves.

A.3.4.8 The SoC identification is rechecked before leaving the OR (UC 18)

AIDC is used to record the end of the surgery by scanning either the primary identification band or, if replaced, the secondary identification band. This is recording and closing the surgery process.

A.4 Machine readable coding to avoid workarounds

A.4.1 General

Recent published studies have shown that there are circumstances where the Individual Providers do not capture (scan) the correct data at the right time and that there is a risk leading to errors. These errors shall be avoided by using AIDC at the point of care.

A.4.2 Use cases

A.4.2.1 Sample taking process (UC 19)

Based on the order sheet, the Individual Provider takes a bio-sample from the SoC using sample tube. This tube is linked to the SoC and the laboratory order sheet. The test tube is usually sent to the laboratory with the order sheet for analysis.

A.4.2.2 Radiology process (UC 20)

The SoC is brought to the radiology department for an examination. The identification band shall be removed. After the examination, and before the SoC leaves the radiology department, a new band is issued.

A.4.3 UC 19 and UC 20 Process flow

Figure A.4 — UC 19 and UC 20 Process flow

A.4.4 Good practice

A.4.4.1 Sample taking process (UC 19)

The Individual Provider scans the GSRN on both the identification band and the laboratory order sheet. Both have the same GSRN, but a different SRIN to distinguish between them. A sample tube label is printed with the GSRN and a new SRIN. The Individual Provider completes the process by scanning the label on the tube after taking the sample. As each carries the GSRN and a different SRIN, the Individual Provider scans each element separately. The Individual Provider is prevented from rescanning the same identity more than once, because the SRIN raises an alert of indicating a multiple scan.

A.4.4.2 Radiology process (UC 20)

The SoC is brought to the radiology department for an examination. The identification band may be cut and stored during the radiology examination. At the end of the examination, the damaged identification band is scanned and used to trigger the issue of a new identification band with a new SRIN. Each of the identification bands carries GSRN and SRIN, so that the system captures the identification band change before and after removal. If the identification band does not need to be cut out, then the process remains based on the initial identification band.

A.5 Machine readable coding in the blood transfusion processes (UC 21 to 24)

A.5.1 General

For several years, machine readable coding has been implemented in the blood transfusion process using the ISBT 128 standard. This standard includes attributes to identify the SoC (transfusion receiver) and the Individual Provider. Although ISBT 128 has been implemented in a large number of countries, the attributes for identifying the SoC has not been adopted widely. The experience of the blood transfusion services is leveraged here to provide implementation recommendations to include and extend beyond these specific processes.

A.5.2 Use cases

A.5.2.1 General

Transfusion involves a number of processes with the safety of each process being dependent on the accuracy and safety of the previous stages. Safely transfusing a blood product relies on the appropriate pre-transfusion analysis of the SoC bio-sample and then selecting a compatible blood product based on the analysis of that sample. The sample should be drawn from the intended recipient SoC and be properly labelled immediately after sampling, and prior to leaving the SoC, and sending to the laboratory.

The best practice requires that

- the Individual Provider (blood taker) is recorded on the pre-transfusion sample label and traceable for at least one-year post transfusion, and
- just prior to transfusion, verifications are performed to ensure that the blood product supplied, and the issue voucher matches the SoC's GSRN on the identification band. The documentation of the verification process (records, written or electronic) is retained indefinitely.

The process below represents a routine transfusion event.

A.5.2.2 Pre-transfusion sample collection (UC 22)

At sample collection, AIDC enables the Individual Provider (blood taker) to identify him/herself and positively identify the intended SoC for transfusion. In the presence of the SoC, a computer-generated barcoded label containing the SoC name and identification is accurately and efficiently produced using that data scanned on SoC's identification band and affixed on the blood sample.

A.5.2.3 Pre-transfusion testing and product selection (UC 23)

The use of barcoded labels on the sample tubes eliminates the need to manually enter SoC identifiers, thereby, eliminating key entry errors and ensuring that after analysis the sample analysis are correctly attributed to the right SoC file. Automated analysers equipped to read the barcodes on the sample tubes likewise eliminate data errors in the laboratory. As well, selected product is assigned to correct SoC when barcoded labels are used.

A.5.2.4 Transfusion (UC 24)

The transfusion standards require vein to vein traceability. In addition, blood products should be scanned at receipt in the care unit. The use of the same AIDC for the blood sample and test process allows verification of the SoC to blood product match. This enables a reduction in the tedious 8-point checklist that shall be completed at the bedside by two professionals.
