Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 22197-4 was prepared by Technical Committee ISO/TC 206, *Fine ceramics*.

ISO 22197 consists of the following parts, under the general title *Fine ceramics (advanced ceramics, advanced technical ceramics)* — *Test method for air-purification performance of semiconducting photocatalytic materials*:

- *Part 1: Removal of nitric oxide*
- *Part 2: Removal of acetaldehyde*
- *Part 3: Removal of toluene*
- *Part 4: Removal of formaldehyde*
- *Part 5: Removal of methyl mercaptan*

Fine ceramics (advanced ceramics, advanced technical ceramics) — Test method for air-purification performance of semiconducting photocatalytic materials —

Part 4: Removal of formaldehyde

1 Scope

This part of ISO 22197 specifies a test method for the determination of the air-purification performance of materials that contain a photocatalyst or have photocatalytic films on the surface, usually made from semiconducting metal oxides, such as titanium dioxide or other ceramic materials, by continuous exposure of a test piece to the model air pollutant under illumination with ultraviolet light (UV-A). This part of ISO 22197 is intended for use with different kinds of materials, such as construction materials in flat sheet, board or plate shape, that are the basic forms of materials for various applications. This part of ISO 22197 also applies to structured filter materials including honeycomb-form, woven and non-woven fabrics, and to plastic or paper materials if they contain ceramic microcrystals and composites. This part of ISO 22197 does not apply to powder or granular photocatalytic materials.

This test method is usually applicable to photocatalytic materials produced for air purification. This method is not suitable for the determination of other performance attributes of photocatalytic materials, i.e. decomposition of water contaminants, self-cleaning, antifogging and antibacterial actions. It concerns the removal of formaldehyde.

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1
photocatalyst
substance that performs one or more functions based on oxidation and reduction reactions under photoirradiation, including decomposition and removal of air and water contaminants, deodorization, and antibacterial, self-cleaning and antifogging actions

3.2
photocatalytic materials
materials in which or on which the photocatalyst is added by coating, impregnation, mixing, etc

Note 1 to entry: Such photocatalytic materials are intended primarily for use as building and road construction materials to obtain the above-mentioned functions

3.3
zero-calibration gas
air that does not contain pollutants (i.e. in which common pollutants are below 0,01 µl/l)

Note 1 to entry: The zero-calibration gas is prepared from indoor air using a laboratory air purification system, or supplied as a synthetic air in a gas cylinder.

3.4
formaldehyde gas
gases of known concentrations used for test and calibration

3.5
test gas
mixture of air and pollutant(s) of known concentration prepared from a standard gas or a zero-calibration gas, to be used for the performance test of a photocatalytic material

Note 1 to entry: The flow rate, concentration, etc. are expressed at the standard state (0 °C, 101,3 kPa) and dry gas basis (exclusion of water vapour).

3.6
dark condition
test condition with no light illumination by the light source for testing and room lightings

Note 1 to entry: Usually the test gas is supplied for comparison with the illuminated reaction.

4 Symbols

For the purposes of this document, the following symbols apply.

f	the flow rate of test gas converted into that at the standard state (l/min, 0 °C, 101,3 kPa, dry gas basis)
ϕ_F	the volume fraction of formaldehyde at the reactor exit (µl/l)
ϕ_{F0}	the supply volume fraction of formaldehyde (µl/l)
n_F	the removal quantity, by test piece, of formaldehyde (µmol)
R_F	the removal percentage, by test piece, of formaldehyde (%)

5 Principle

This part of ISO 22197 concerns the development, comparison, quality assurance, characterization, reliability, and design data generation of photocatalytic materials. The method described is intended to obtain the air-purification performance of photocatalytic materials by exposing a test piece to model polluted air under irradiation by ultraviolet (UV-A) light. Formaldehyde (HCHO) is chosen

because it is a typical indoor air pollutant that causes the so-called sick-building syndrome. The test piece, placed in a flow-type photoreactor, is activated by UV irradiation, and adsorbs and oxidizes gas-phase formaldehyde to form carbon dioxide (CO₂) and other oxidation products. The air purification performance is determined from the net amount of formaldehyde removed by the test piece (μmol). The simple adsorption of HCHO by the test piece (not due to photocatalysis) is evaluated by tests in the dark. However, some test pieces absorb formaldehyde very strongly, and a stable concentration of formaldehyde may not be attained in the designated time of test. The photocatalytic activity may depend on physical and chemical properties of pollutants mainly due to the adsorption process involved. For a better evaluation of air purification performance of photocatalytic materials, it is recommended to combine one or more suitable test methods as provided in other parts of ISO 22197.

6 Apparatus

6.1 Test equipment

The test equipment enables a photocatalytic material to be examined for its pollutant-removal capability by supplying the test gas continuously, while providing photoirradiation to activate the photocatalyst. It is the same as that used in the test method for the removal of nitric oxide (ISO 22197-1) and consists of a test gas supply, a photoreactor, a light source, and pollutant-measurement equipment. Since low concentrations of pollutants are to be tested, the system shall be constructed with materials of low absorption and resistant to ultraviolet (UV) radiation, for example, acrylic resin, stainless steel, glass and fluorocarbon polymers. An example of a test system is shown in [Figure 1](#).

Figure 2 — Cross-sectional views of photoreactor (axial)**6.2 Test gas supply**

The test gas supply provides air polluted with model contaminant at a predetermined concentration, temperature and humidity, and supplies it continuously to the photoreactor. It consists of flow regulators, a humidifier, gas mixers, etc. The flow rate of each gas should be within 5 % of the designated value,

which is easily attained by using thermal mass-flow controllers with knowledge of temperature and gas type at calibration in accordance with ISO 6145-7. The expression of gas flow rate in this part of ISO 22197 is that converted to the standard state (0 °C, 101,3 kPa and dry gas basis). Typical capacities of flow controller for pollutant gas, dry air and wet air are 200 ml/min, 2000 ml/min and 2000 ml/min, respectively. The standard formaldehyde gas in a cylinder, normally balanced with nitrogen, shall have a volume fraction of about 20 µl/l.

6.3 Photoreactor

The photoreactor holds a planar test piece within a 50 mm wide trough, with its surface parallel to an optical window for photoirradiation. The reactor shall be fabricated from materials that adsorb little test gas and withstand irradiation of near-UV light. The test piece shall be separated from the window by a $5,0 \text{ mm} \pm 0,5 \text{ mm}$ thick air layer. The test gas shall pass only through the space between the test piece and the window. This gap shall be accurately set up according to the thickness of the test piece, for example by using height-adjusting plates with different thicknesses, as shown in [Figure 2 a](#)). When a filter-type material is tested, an alternative type of test-piece holder shall be used, which holds the test piece while allowing the test gas to pass through the cells of the filter under irradiation [[Figure 2 b](#)]). Quartz or borosilicate glass that absorbs minimal light at wavelengths longer than 300 nm shall be used for the window.

6.4 Light source

The light source shall provide UV-A irradiation within a wavelength range of 300 nm to 400 nm. Suitable sources include the so-called blacklight (BL) and blacklight blue (BLB) fluorescent lamps, with a maximum at 351 nm, as specified in ISO 4892-3 and ISO 10677. The test piece shall be irradiated uniformly through the window by the light source. In the case of testing honeycomb-form photocatalysts, the light source shall irradiate one face of the test piece. A light source that requires warming up shall be equipped with a shutter. The distance between the light source and the reactor shall be adjusted so that the UV irradiance (300 nm to 400 nm) at the sample surface is $10 \text{ W/m}^2 \pm 0,5 \text{ W/m}^2$. The irradiance along the length of the test piece shall also be constant within $\pm 5 \%$. The UV irradiance shall be measured with a radiometer which conforms to ISO 10677. The reactor shall be shielded from external light if necessary.

6.5 Analytical system

The test gas is sampled using a sampling cartridge, pump and flow controller, as specified in ISO 16000-3. The concentration of formaldehyde shall be determined by 2,4-dinitrophenylhydrazine-derivatised high-performance liquid chromatography (DNPH-HPLC). The reagents, equipment and procedure as specified in ISO 16000-3 shall be used. Other analytical methods that give equivalent or better performance can be used.

7 Test piece

The test piece shall be a flat material or a honeycomb filter of $49,5 \text{ mm} \pm 0,5 \text{ mm}$ wide and $99,5 \text{ mm} \pm 0,5 \text{ mm}$ long. It may be cut to these dimensions from a larger bulk material or coated sheet, or may be specially prepared for the test by coating a pre-cut substrate. The thickness of the test piece shall ideally be less than 5 mm, in order to minimize the contribution from the side faces. If thicker test pieces are to be tested, the side faces shall be sealed with an inert material before testing. The honeycomb test piece shall not be thicker than 20 mm.

8 Procedure

8.1 General aspects

The test procedure consists of pretreatment of the test piece, an adsorption process in the dark, and measurements of removal of formaldehyde under photoirradiation. An example of the concentration change of formaldehyde during the test is shown in [Figure 3](#). Some test pieces may not give accurate

removal of formaldehyde due to lower photocatalytic activity. In this case, loading of formaldehyde per test piece can be reduced following the procedure in [Clause 10](#).

Key

- X Time (min)
- Y Concentration of formaldehyde (µl/l)
- 1 Irradiation start
- 2 Irradiation stop

Figure 3 — Typical trace of formaldehyde concentration during the test operation

8.2 Pretreatment of test piece

Irradiate the test piece with an ultraviolet lamp for at least 16 h (up to 24 h) to decompose residual organic matter on the test piece. The UV irradiance at the sample surface should be high enough to secure complete decomposition of organic matter (15 W/m² or higher). If the test pieces are not to be tested immediately after this pretreatment, they shall be kept in an airtight container.

8.3 Preparation for the test

8.3.1 Adjust the test gas supply beforehand so that it can stably supply the test gas containing $1,0 \pm 0,1$ (µl/l) of formaldehyde and $1,56 \% \pm 0,16 \%$ of volume fraction of water vapour at $25,0 \text{ }^{\circ}\text{C} \pm 2,5 \text{ }^{\circ}\text{C}$. This water-vapour volume fraction is equivalent to a relative humidity of 50 % at 25 °C. Set the flow rate to be 3,0 l/min (0 °C, 101,3 kPa, dry gas basis) at the entrance of the photoreactor. Measure and record the irradiance from the light source. For the light source that requires warming up, turn the power on well before the measurement of irradiance and irradiation for the acetaldehyde removal test. Use the shutter appropriately to avoid unnecessary irradiation to the photoreactor.

8.3.2 Place the test piece in the centre of the photoreactor and attach the glass window after adjusting the air layer between the test piece and window to be $5,0 \text{ mm} \pm 0,5 \text{ mm}$ thick. If necessary, height-adjusting plates are used for this purpose, and adjusting the height before and after of the test piece to be within 1,0 mm difference based on the top of the test piece. Check that the reactor is sealed by visual examination of the sealing material, such as an O-ring to tightly contact the glass window.

8.4 Pretest

The concentration of formaldehyde cannot be obtained instantaneously by the DNPH-HPLC method. Therefore, the time of the adsorption of formaldehyde reaching saturation in a dark condition cannot be confirmed during the test. For this reason, the following pretest shall be carried out. If the time for saturation can be confirmed during the test, there is no need for the pretest.

After pretreatment of the test piece in 8.2 and preparation for the test in 8.3, introduce the test gas into the reactor. Measure the concentration of formaldehyde under the dark condition every 15 min for 90 min. When the concentration at the outlet of the reactor becomes the same as the supply gas concentration within 30 min, then that time may be the time of the dark condition. When the concentration of formaldehyde is less than 90 % of the concentration after 30 min, the time of the dark condition shall be the time when the concentration exceeds 90 % for the first time. When the concentration of formaldehyde is still less than 90 % of the concentration after 90 min, then this part of ISO 22197 shall not apply.

8.5 Removal test

8.5.1 Follow the pretreatment procedure as in 8.2 and preparation as in 8.3.

8.5.2 If the pretest in 8.4 has been already carried out, introduce the test gas into photoreactor under dark conditions for the previously confirmed time. If the pretest has not been done yet, carry out the following procedure. Introduce the test gas into the photoreactor and record the formaldehyde concentration for 30 min under dark conditions to observe the absorption process of the test piece. If the formaldehyde concentration matches the same level of concentration of the supply concentration, at that point, initiate light irradiation. However, after 30 min and when the formaldehyde concentration is still far below 90 % of the supply concentration, continue until it exceeds 90 %. If it does not exceed 90 % even after 90 min, this test method shall not apply.

8.5.3 Maintain the gas flow and commence irradiation of the test piece. For the light source that requires warming up, the same procedure shall be applied as described in 8.3.1. Record the concentration under irradiation for 3 h. When the photocatalytic decomposition begins, the concentration decreases as in Figure 3 and eventually becomes constant. The formaldehyde concentration shall be measured at more than one point in 1 h. Measurement shall be made at more than 3 points as in the last hour (120 min – 180 min after the start of irradiation). The concentration of formaldehyde shall be obtained by the average value based on the concentrations measured in the last hour.

8.5.4 Stop the gas supply to the reactor and remove the test piece from the reactor.

NOTE When the test piece that was used in the pretest is going to be reused in the actual test, the pretreatment in 8.2 shall be repeated.

9 Calculation

The test results shall be calculated as follows. The calculated values are usually rounded to one decimal place according to ISO 80000-1. The observed concentration of formaldehyde before water vapour correction shall be used for calculation. The flow rate of test gas f is 3,0 l/min normalized for 0 °C, 101,3 kPa and dry gas basis, and is then multiplied by a factor of 1,016 for water vapour correction.

The removal percentage of formaldehyde (R_F) is calculated by Formula (1). When R_F is either below 5 % or more than 95 %, R_F is expressed as “below 5 %” or “more than 95 %”, respectively. Then, the quantity of formaldehyde removed (n_F) is calculated by Formula (2). When R_F is either below 5 % or more than 95 %, n_F is expressed as “below (0,136 $\phi_{F0} f$) μmol ” or “more than (2,585 $\phi_{F0} f$) μmol ”, respectively.

$$R_F = \frac{\phi_{F0} - \phi_F}{\phi_{F0}} \times 100 \quad (1)$$
