Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of the joint technical committee is to prepare International Standards. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 17203 was prepared by ANSI INCITS (as INCITS 469:2010) and was adopted, under a special “fast-track procedure”, by Joint Technical Committee ISO/IEC JTC 1, *Information technology*, in parallel with its approval by the national bodies of ISO and IEC.

Approved July 20, 2010

American National Standards Institute, Inc.

American National Standard

Approval of an American National Standard requires review by ANSI that the requirements for due process, consensus, and other criteria for approval have been met by the standards developer.

Consensus is established when, in the judgement of the ANSI Board of Standards Review, substantial agreement has been reached by directly and materially affected interests. Substantial agreement means much more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered, and that a concerted effort be made towards their resolution.

The use of American National Standards is completely voluntary; their existence does not in any respect preclude anyone, whether he has approved the standards or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standards.

The American National Standards Institute does not develop standards and will in no circumstances give an interpretation of any American National Standard. Moreover, no person shall have the right or authority to issue an interpretation of an American National Standard in the name of the American National Standards Institute. Requests for interpretations should be addressed to the secretariat or sponsor whose name appears on the title page of this standard.

CAUTION NOTICE: This American National Standard may be revised or withdrawn at any time. The procedures of the American National Standards Institute require that action be taken periodically to reaffirm, revise, or withdraw this standard. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute.

CAUTION: The developers of this standard have requested that holders of patents that may be required for the implementation of the standard disclose such patents to the publisher. However, neither the developers nor the publisher have undertaken a patent search in order to identify which, if any, patents may apply to this standard. As of the date of publication of this standard and following calls for the identification of patents that may be required for the implementation of the standard, no such claims have been made. No further patent search is conducted by the developer or publisher in respect to any standard it processes. No representation is made or implied that licenses are not required to avoid infringement in the use of this standard.

Foreword (This foreword is not part of American National Standard INCITS 469-2010.)

The *Open Virtualization Format (OVF) Specification* describes an open, secure, portable, efficient and extensible format for the packaging and distribution of software to be run in virtual machines. The key properties of the format are as follows:

- **Optimized for distribution:** OVF supports content verification and integrity checking based on industry-standard public key infrastructure, and it provides a basic scheme for management of software licensing.
- **Optimized for a simple, automated user experience:** OVF supports validation of the entire package and each virtual machine or metadata component of the OVF during the installation phases of the virtual machine (VM) lifecycle management process. It also packages with the package relevant user-readable descriptive information that a virtualization platform can use to streamline the installation experience.
- **Supports both single VM and multiple-VM configurations:** OVF supports both standard single VM packages and packages containing complex, multi-tier services consisting of multiple interdependent VMs.
- **Portable VM packaging:** OVF is virtualization platform neutral, while also enabling platform-specific enhancements to be captured. It supports the full range of virtual hard disk formats used for hypervisors today, and it is extensible, which allow it to accommodate formats that may arise in the future. Virtual machine properties are captured concisely and accurately.
- **Vendor and platform independent:** OVF does not rely on the use of a specific host platform, virtualization platform, or guest operating system.
- **Extensible:** OVF is immediately useful - and extensible. It is designed to be extended as the industry moves forward with virtual appliance technology. It also supports and permits the encoding of vendor-specific metadata to support specific vertical markets.
- **Localizable:** OVF supports user-visible descriptions in multiple locales, and it supports localization of the interactive processes during installation of an appliance. This capability allows a single packaged appliance to serve multiple market opportunities.
- **Open standard:** OVF has arisen from the collaboration of key vendors in the industry, and it is developed in an accepted industry forum as a future standard for portable virtual machines.

It is not an explicit goal for OVF to be an efficient execution format. A hypervisor is allowed but not required to run software in virtual machines directly out of the Open Virtualization Format.

This standard contains four annexes. Annex C is normative and is considered part of this standard. Annexes A, B, and D are informative and are not considered part of this standard.

Requests for interpretation, suggestions for improvement or addenda, or defect reports are welcome. They should be sent to InterNational Committee for Information Technology Standards (INCITS), ITI, 1101 K Street, NW, Suite 610, Washington, DC 20005.

This standard was processed and approved for submittal to ANSI by INCITS. Committee approval of this standard does not necessarily imply that all committee members voted for its approval. At the time it approved this standard, INCITS had the following members:

Don Wright, Chair
Jennifer Garner, Secretary

American National Standard for Information Technology –

Open Virtualization Format (OVF) Specification

1 Scope

The *Open Virtualization Format (OVF) Specification* describes an open, secure, portable, efficient and extensible format for the packaging and distribution of software to be run in virtual machines.

2 Normative References

The following standards contain provisions which, through reference in this text, constitute provisions of this American National Standard. All standards are subject to revision, and parties to agreements based on this American National Standard are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below.

3 Terms and Definitions

For the purposes of this document, the following terms and definitions apply.

3.1

can

used for statements of possibility and capability, whether material, physical, or causal

3.2

cannot

used for statements of possibility and capability, whether material, physical, or causal

3.3

conditional

indicates requirements to be followed strictly to conform to the document when the specified conditions are met

3.4

mandatory

indicates requirements to be followed strictly to conform to the document and from which no deviation is permitted

3.5

may

indicates a course of action permissible within the limits of the document

3.6

need not

indicates a course of action permissible within the limits of the document

3.7

optional

indicates a course of action permissible within the limits of the document

3.8

shall

indicates requirements to be followed strictly to conform to the document and from which no deviation is permitted

3.9

shall not

indicates requirements to be followed strictly to conform to the document and from which no deviation is permitted

3.10

should

indicates that among several possibilities, one is recommended as particularly suitable, without mentioning or excluding others, or that a certain course of action is preferred but not necessarily required

3.11**should not**

indicates that a certain possibility or course of action is deprecated but not prohibited

3.12**appliance**

see **virtual appliance** (3.18)

3.13**deployment platform**

the product that installs an OVF package

3.14**guest software**

the software, stored on the virtual disks, that runs when a virtual machine is powered on. The guest is typically an operating system and some user-level applications and services.

3.15**OVF package**

OVF XML descriptor file accompanied by zero or more files

3.16**OVF descriptor**

OVF XML descriptor file

3.17**platform**

see **deployment platform** (3.13)

3.18**virtual appliance**

a service delivered as a complete software stack installed on one or more virtual machines. A virtual appliance is typically expected to be delivered in an OVF package.

3.19**virtual hardware**

the hardware (including the CPU, controllers, Ethernet devices, and disks) that is seen by the guest software

3.20**virtual machine**

the complete environment that supports the execution of guest software. A virtual machine is a full encapsulation of the virtual hardware, virtual disks, and the metadata associated with it. Virtual machines allow multiplexing of the underlying physical machine through a software layer called a hypervisor.

3.21**virtual machine collection**

a service comprised of a set of virtual machines

The service can be a simple set of one or more virtual machines, or it can be a complex service built out of a combination of virtual machines and other virtual machine collections. Because virtual machine collections can be composed, it enables complex nested components.

4 Symbols and Abbreviated Terms

The following symbols and abbreviations are used in this document.

4.1.1

CIM

Common Information Model

4.1.2

IP

Internet Protocol

4.1.3

OVF

Open Virtualization Format

4.1.4

VM

Virtual Machine

5 OVF Packages

5.1 OVF Package Structure

An OVF package shall consist of the following files:

- one OVF descriptor with extension `.ovf`
- zero or one OVF manifest with extension `.mf`
- zero or one OVF certificate with extension `.cert`
- zero or more disk image files
- zero or more additional resource files, such as ISO images

The file extensions `.ovf`, `.mf` and `.cert` shall be used.

EXAMPLE 1: The following list of files is an example of an OVF package:

```
package.ovf
package.mf
de-DE-resources.xml
vmdisk1.vmdk
vmdisk2.vmdk
resource.iso
```

NOTE: The previous example uses VMDK disk files, but multiple disk formats are supported.

An OVF package can be stored as either a single unit or a set of files, as described in 5.3 and 5.4. Both modes shall be supported.

An OVF package may have a manifest file containing the SHA-1 digests of individual files in the package. The manifest file shall have an extension `.mf` and the same base name as the `.ovf` file and be a sibling of the `.ovf` file. If the manifest file is present, a consumer of the OVF package shall verify the

digests by computing the actual SHA-1 digests and comparing them with the digests listed in the manifest file.

The syntax definitions below use ABNF with the exceptions listed in ANNEX A.

The format of the manifest file is as follows:

```
manifest_file = *( file_digest )
file_digest   = algorithm "(" file_name ")" "=" sp digest nl
algorithm     = "SHA1"
digest        = 40( hex-digit ) ; 160-bit digest in 40-digit hexadecimal
hex-digit     = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9" | "a" |
               "b" | "c" | "d" | "e" | "f"
sp            = %x20
nl            = %x0A
```

EXAMPLE 2: The following example show the partial contents of a manifest file:

```
SHA1(package.ovf)= 237de026fb285b85528901da058475e56034da95
SHA1(vmdisk1.vmdk)= 393a66df214e192ffbfedb78528b5be75cc9e1c3
```

An OVF package may be signed by signing the manifest file. The digest of the manifest file is stored in a certificate file with extension .cert file along with the base64-encoded X.509 certificate. The .cert file shall have the same base name as the .ovf file and be a sibling of the .ovf file. A consumer of the OVF package shall verify the signature and should validate the certificate. The format of the certificate file shall be as follows:

```
certificate_file = manifest_digest certificate_part
manifest_digest = algorithm "(" file_name ")" "=" sp signed_digest nl
algorithm       = "SHA1"
signed_digest    = *( hex-digit )
certificate_part = certificate_header certificate_body certificate_footer
certificate_header = "-----BEGIN CERTIFICATE-----" nl
certificate_footer = "-----END CERTIFICATE-----" nl
certificate_body  = base64-encoded-certificate nl
                  ; base64-encoded-certificate is a base64-encoded X.509
                  ; certificate, which may be split across multiple lines
hex-digit        = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9" | "a" |
               "b" | "c" | "d" | "e" | "f"
sp               = %x20
nl               = %x0A
```

EXAMPLE 3: The following list of files is an example of a signed OVF package:

```
package.ovf
package.mf
package.cert
de-DE-resources.xml
vmdisk1.vmdk
vmdisk2.vmdk
resource.iso
```

EXAMPLE 4: The following example shows the contents of a sample OVF certification file, where the SHA1 digest of the manifest file has been signed with a 512 bit key:

```
SHA1(package.mf)= 7f4b8efb8fe20c06df1db68281a63f1b088e19dbf00e5af9db5e8e3e319de
7019db88a3bc699bab6ccd9e09171e21e88ee20b5255cec3fc28350613b2c529089
```

```

Ims6ZOZB
-----END CERTIFICATE-----

```

The manifest and certificate files, when present, shall not be included in the References section of the OVF descriptor (see 7.1). This ensures that the OVF descriptor content does not depend on whether the OVF package has a manifest or is signed, and the decision to add a manifest or certificate to a package can be deferred to a later stage.

The file extensions .mf and .cert may be used for other files in an OVF package, as long as they do not occupy the sibling URLs or path names where they would be interpreted as the package manifest or certificate.

5.2 Virtual Disk Formats

OVF does not require any specific disk format to be used, but to comply with this specification the disk format shall be given by a URI which identifies an unencumbered specification on how to interpret the disk format. The specification need not be machine readable, but it shall be static and unique so that the URI may be used as a key by software reading an OVF package to uniquely determine the format of the disk. The specification shall provide sufficient information so that a skilled person can properly interpret the disk format for both reading and writing of disk data. It is recommended that these URIs are resolvable.

5.3 Distribution as a Single File

An OVF package may be stored as a single file using the TAR format. The extension of that file shall be .ova (open virtual appliance or application).

EXAMPLE: The following example shows a sample filename for an OVF package of this type:

```
D:\virtualappliances\myapp.ova
```

For OVF packages stored as single file, all file references in the OVF descriptor shall be relative-path references and shall point to files included in the TAR archive. Relative directories inside the archive are allowed, but relative-path references shall not contain “..” dot-segments.

Ordinarily, a TAR extraction tool would have to scan the whole archive, even if the file requested is found at the beginning, because replacement files can be appended without modifying the rest of the archive. For OVF TAR files, duplication is not allowed within the archive. In addition, the files shall be in the following order inside the archive:

- 1) OVF descriptor
- 2) OVF manifest (optional)
- 3) OVF certificate (optional)
- 4) The remaining files shall be in the same order as listed in the References section (see 7.1). Note that any external string resource bundle files for internationalization shall be first in the References section (see clause 10).

- 5) OVF manifest (optional)
- 6) OVF certificate (optional)

Note that the certificate file is optional. If no certificate file is present, the manifest file is also optional. If the manifest or certificate files are present, they shall either both be placed after the OVF descriptor, or both be placed at the end of the archive.

For deployment, the ordering restriction ensures that it is possible to extract the OVF descriptor from an OVF TAR file without scanning the entire archive. For generation, the ordering restriction ensures that an OVF TAR file can easily be generated on-the-fly. The restrictions do not prevent OVF TAR files from being created using standard TAR packaging tools.

The TAR format used shall comply with the USTAR (Uniform Standard Tape Archive) format as defined by the POSIX IEEE 1003.1 standards group.

5.4 Distribution as a Set of Files

An OVF package can be made available as a set of files, for example on a standard Web server.

EXAMPLE: An example of an OVF package as a set of files on Web server follows:

```
http://mywebsite/virtualappliances/package.ovf
http://mywebsite/virtualappliances/vmdisk1.vmdk
http://mywebsite/virtualappliances/vmdisk2.vmdk
http://mywebsite/virtualappliances/resource.iso
http://mywebsite/virtualappliances/de-DE-resources.xml
```

6 OVF Descriptor

All metadata about the package and its contents is stored in the OVF descriptor. This is an extensible XML document for encoding information, such as product details, virtual hardware requirements, and licensing.

The dsp8023_1.1.0.xsd XML schema definition file for the OVF descriptor contains the elements and attributes.

Clauses 7, 8, and 9, describe the semantics, structure, and extensibility framework of the OVF descriptor. These clauses are not a replacement for reading the schema definitions, but they complement the schema definitions.

The XML document of an OVF descriptor shall contain one Envelope element, which is the only element allowed at the top level.

The XML namespaces used in this specification are listed in Table 1. The choice of any namespace prefix is arbitrary and not semantically significant.

Table 1 – XML Namespace Prefixes

Prefix	XML Namespace
ovf	http://schemas.dmtf.org/ovf/envelope/1
ovfenv	http://schemas.dmtf.org/ovf/environment/1
rasd	http://schemas.dmtf.org/wbem/wscim/1/cim-schema/2/CIM_ResourceAllocationSettingData
vssd	http://schemas.dmtf.org/wbem/wscim/1/cim-schema/2/CIM_VirtualSystemSettingData
cim	http://schemas.dmtf.org/wbem/wscim/1/common

7 Envelope Element

The Envelope element describes all metadata for the virtual machines (including virtual hardware), as well as the structure of the OVF package itself.

The outermost level of the envelope consists of the following parts:

- A version indication, defined by the XML namespace URIs.
- A list of file references to all external files that are part of the OVF package, defined by the References element and its File child elements. These are typically virtual disk files, ISO images, and internationalization resources.
- A metadata part, defined by section elements, as defined in clause 9.
- A description of the content, either a single virtual machine (VirtualSystem element) or a collection of multiple virtual machines (VirtualSystemCollection element).
- A specification of message resource bundles for zero or more locales, defined by a Strings element for each locale.

EXAMPLE: An example of the structure of an OVF descriptor with the top-level Envelope element follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:vssd="http://schemas.dmtf.org/wbem/wscim/1/cim-
schema/2/CIM_VirtualSystemSettingData"
  xmlns:rasd="http://schemas.dmtf.org/wbem/wscim/1/cim-
schema/2/CIM_ResourceAllocationSettingData"
  xmlns:ovf="http://schemas.dmtf.org/ovf/envelope/1"
  xmlns="http://schemas.dmtf.org/ovf/envelope/1"
  xml:lang="en-US">
  <References>
    <File ovf:id="de-DE-resources.xml" ovf:size="15240"
      ovf:href="http://mywebsite/virtualappliances/de-DE-resources.xml"/>
    <File ovf:id="file1" ovf:href="vmdisk1.vmdk" ovf:size="180114671"/>
    <File ovf:id="file2" ovf:href="vmdisk2.vmdk" ovf:size="4882023564"
ovf:chunkSize="2147483648"/>
    <File ovf:id="file3" ovf:href="resource.iso" ovf:size="212148764"
ovf:compression="gzip"/>
    <File ovf:id="icon" ovf:href="icon.png" ovf:size="1360"/>
  </References>
```

```

<!-- Describes meta-information about all virtual disks in the package -->
<DiskSection>
  <Info>Describes the set of virtual disks</Info>
  <!-- Additional section content -->
</DiskSection>
<!-- Describes all networks used in the package -->
<NetworkSection>
  <Info>List of logical networks used in the package</Info>
  <!-- Additional section content -->
</NetworkSection>
<SomeSection ovf:required="false">
  <Info>A plain-text description of the content</Info>
  <!-- Additional section content -->
</SomeSection>
<!-- Additional sections can follow -->
<VirtualSystemCollection ovf:id="Some Product">
  <!-- Additional sections including VirtualSystem or VirtualSystemCollection-->
</VirtualSystemCollection >
<Strings xml:lang="de-DE">
  <!-- Specification of message resource bundles for de-DE locale -->
</Strings>
</Envelope>

```

The optional `xml:lang` attribute on the `Envelope` element shall specify the default locale for messages in the descriptor. The optional `Strings` elements shall contain string resource bundles for different locales. See clause 10 for more details on internationalization support.

7.1 File References

The file reference part defined by the `References` element allows a tool to easily determine the integrity of an OVF package without having to parse or interpret the entire structure of the descriptor. Tools can safely manipulate (for example, copy or archive) OVF packages with no risk of losing files.

External string resource bundle files for internationalization shall be placed first in the `References` element, see clause 10 for details.

Each `File` element in the reference part shall be given an identifier using the `ovf:id` attribute. The identifier shall be unique inside an OVF package. Each `File` element shall be specified using the `ovf:href` attribute, which shall contain a URL. Relative-path references and the URL schemes "file", "http", and "https" shall be supported, see [RFC1738](#) and [RFC3986](#). Other URL schemes should not be used. If no URL scheme is specified, the value of the `ovf:href` attribute shall be interpreted as a path name of the referenced file that is relative to the location of the OVF descriptor itself. The relative path name shall use the syntax of relative-path references in [RFC3986](#). The referenced file shall exist. Two different `File` elements shall not reference the same file with their `ovf:href` attributes.

The size of the referenced file may be specified using the `ovf:size` attribute. The unit of this attribute is always bytes. If present, the value of the `ovf:size` attribute shall match the actual size of the referenced file.

Each file referenced by a `File` element may be compressed using gzip (see [RFC1952](#)). When a `File` element is compressed using gzip, the `ovf:compression` attribute shall be set to "gzip". Otherwise, the `ovf:compression` attribute shall be set to "identity" or the entire attribute omitted. Alternatively, if the href is an HTTP or HTTPS URL, then the compression may be specified by the HTTP server by using the HTTP header `Content-Encoding: gzip` (see [RFC2616](#)). Using HTTP content encoding in combination with the `ovf:compression` attribute is allowed, but in general does not improve the

compression ratio. When compression is used, the `ovf:size` attribute shall specify the size of the actual compressed file.

Files referenced from the reference part may be split into chunks to accommodate file size restrictions on certain file systems. Chunking shall be indicated by the presence of the `ovf:chunkSize` attribute; the value of `ovf:chunkSize` shall be the size of each chunk, except the last chunk, which may be smaller.

When `ovf:chunkSize` is specified, the `File` element shall reference a chunk file representing a chunk of the entire file. In this case, the value of the `ovf:href` attribute specifies only a part of the URL, and the syntax for the URL resolving to the chunk file is as follows. The syntax uses ABNF with the exceptions listed in ANNEX A.

```
chunk-url      = href-value "." chunk-number
chunk-number   = 9(decimal-digit)
decimal-digit  = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9"
```

In this syntax, `href-value` is the value of the `ovf:href` attribute, and `chunk-number` is the 0-based position of the chunk starting with the value 0 and increases with increments of 1 for each chunk.

Chunking can be combined with compression, the entire file is then compressed before chunking and each chunk shall be an equal slice of the compressed file, except for the last chunk which may be smaller.

If the OVF package has a manifest file, the file name in the manifest entries shall match the value of the `ovf:href` attribute for the file, except if the file is split into multiple chunks, in which case the `chunk-url` shall be used, and the manifest file shall contain an entry for each individual chunk. For chunked files, the manifest file is allowed to contain an entry for the entire file; if present this digest shall also be verified.

EXAMPLE 1: The following example shows different types of file references:

```
<File ovf:id="disk1" ovf:href="disk1.vmdk"/>
<File ovf:id="disk2" ovf:href="disk2.vmdk" ovf:size="5368709120"
      ovf:chunkSize="2147483648"/>
<File ovf:id="iso1" ovf:href="resources/image1.iso"/>
<File ovf:id="iso2" ovf:href="http://mywebsite/resources/image2.iso"/>
```

EXAMPLE 2: The following example shows manifest entries corresponding to the file references above:

```
SHA1(disk1.vmdk)= 3e19644ec2e806f38951789c76f43e4a0ec7e233
SHA1(disk2.vmdk.000000000)= 4f7158731ff434380bf217da248d47a2478e79d8
SHA1(disk2.vmdk.000000001)= 12849daeeaf43e7a89550384d26bd437bb8defaf
SHA1(disk2.vmdk.000000002)= 4cdd21424bd9eeafa4c42112876217de2ee5556d
SHA1(resources/image1.iso)= 72b37ff3fdd09f2a93f1b8395654649b6d06b5b3
SHA1(http://mywebsite/resources/image2.iso)=
d3c2d179011c970615c5cf10b30957d1c4c968ad
```

7.2 Content Element

Virtual machine configurations in an OVF package are represented by a `VirtualSystem` or `VirtualSystemCollection` element. These elements shall be given an identifier using the `ovf:id` attribute. Direct child elements of a `VirtualSystemCollection` shall have unique identifiers.

In the OVF schema, the `VirtualSystem` and `VirtualSystemCollection` elements are part of a substitution group with the `Content` element as head of the substitution group. The `Content` element is abstract and cannot be used directly. The OVF descriptor shall have one or more `Content` elements.

The `VirtualSystem` element describes a single virtual machine and is simply a container of section elements. These section elements describe virtual hardware, resources, and product information and are described in detail in clauses 8 and 9.

The structure of a `VirtualSystem` element is as follows:

```
<VirtualSystem ovf:id="simple-app">
  <Info>A virtual machine</Info>
  <Name>Simple Appliance</Name>
  <SomeSection>
    <!-- Additional section content -->
  </SomeSection>
  <!-- Additional sections can follow -->
</VirtualSystem>
```

The `VirtualSystemCollection` element is a container of multiple `VirtualSystem` or `VirtualSystemCollection` elements. Thus, arbitrary complex configurations can be described. The section elements at the `VirtualSystemCollection` level describe appliance information, properties, resource requirements, and so on, and are described in detail in clause 9.

The structure of a `VirtualSystemCollection` element is as follows:

```
<VirtualSystemCollection ovf:id="multi-tier-app">
  <Info>A collection of virtual machines</Info>
  <Name>Multi-tiered Appliance</Name>
  <SomeSection>
    <!-- Additional section content -->
  </SomeSection>
  <!-- Additional sections can follow -->
  <VirtualSystem ovf:id="...">
    <!-- Additional sections -->
  </VirtualSystem>
  <!-- Additional VirtualSystem or VirtualSystemCollection elements can follow-->
</VirtualSystemCollection>
```

All elements in the Content substitution group shall contain an `Info` element and may contain a `Name` element. The `Info` element contains a human readable description of the meaning of this entity. The `Name` element is an optional localizable display name of the content. See clause 10 for details on how to localize the `Info` and `Name` element.

7.3 Extensibility

This specification allows custom meta-data to be added to OVF descriptors in several ways:

- New section elements may be defined as part of the `Section` substitution group, and used where the OVF schemas allow sections to be present. All subtypes of `Section` contain an `Info` element that contains a human readable description of the meaning of this entity. The values of `Info` elements can be used, for example, to give meaningful warnings to users when a section is being skipped, even if the parser does not know anything about the section. See clause 10 for details on how to localize the `Info` element.
- The OVF schemas use an open content model, where all existing types may be extended at the end with additional elements. Extension points are declared in the OVF schemas with `xs:any` declarations with `namespace="##other"`.
- The OVF schemas allow additional attributes on existing types.

Custom extensions shall not use XML namespaces defined in this specification. This applies to both custom elements and custom attributes.

On custom elements, a Boolean `ovf:required` attribute specifies whether the information in the element is required for correct behavior or optional. If not specified, the `ovf:required` attribute defaults to TRUE. A consumer of an OVF package that detects an extension that is required and that it does not understand shall fail.

For known Section elements, if additional child elements that are not understood are found and the value of their `ovf:required` attribute is TRUE, the consumer of the OVF package shall interpret the entire section as one it does not understand. The check is not recursive; it applies only to the direct children of the Section element.

This behavior ensures that older parsers reject newer OVF specifications, unless explicitly instructed not to do so.

On custom attributes, the information in the attribute shall not be required for correct behavior.

EXAMPLE 1:

```
<!-- Optional custom section example -->
<othersns:IncidentTrackingSection ovf:required="false">
  <Info>Specifies information useful for incident tracking purposes</Info>
  <BuildSystem>Acme Corporation Official Build System</BuildSystem>
  <BuildNumber>102876</BuildNumber>
  <BuildDate>10-10-2008</BuildDate>
</othersns:IncidentTrackingSection>
```

EXAMPLE 2:

```
<!-- Open content example (extension of existing type) -->
<AnnotationSection>
  <Info>Specifies an annotation for this virtual machine</Info>
  <Annotation>This is an example of how a future element (Author) can still be
    parsed by older clients</Annotation>
  <!-- AnnotationSection extended with Author element -->
  <othersns:Author ovf:required="false">John Smith</othersns:Author>
</AnnotationSection>
```

EXAMPLE 3:

```
<!-- Optional custom attribute example -->
<Network ovf:name="VM network" othersns:desiredCapacity="1 Gbit/s">
  <Description>The main network for VMs</Description>
</Network>
```

7.4 Conformance

This specification defines three conformance levels for OVF descriptors, with 1 being the highest level of conformance:

- OVF descriptor uses only sections and elements and attributes that are defined in this specification.
Conformance Level: 1.
- OVF descriptor uses custom sections or elements or attributes that are not defined in this specification, and all such extensions are optional as defined in 7.3.
Conformance Level: 2.
- OVF descriptor uses custom sections or elements that are not defined in this specification and at least one such extension is required as defined in 7.3. The definition of all required extensions shall be publicly available in an open and unencumbered XML Schema. The complete

specification may be inclusive in the XML schema or available as a separate document.
Conformance Level: 3.

The use of conformance level 3 limits portability and should be avoided if at all possible.

The conformance level is not specified directly in the OVF descriptor but shall be determined by the above rules.

8 Virtual Hardware Description

8.1 VirtualHardwareSection

Each VirtualSystem element may contain one or more VirtualHardwareSection elements, each of which describes the virtual hardware required by the virtual system. The virtual hardware required by a virtual machine is specified in VirtualHardwareSection elements. This specification supports abstract or incomplete hardware descriptions in which only the major devices are described. The hypervisor is allowed to create additional virtual hardware controllers and devices, as long as the required devices listed in the descriptor are realized.

This virtual hardware description is based on the CIM classes CIM_VirtualSystemSettingData and CIM_ResourceAllocationSettingData. The XML representation of the CIM model is based on the WS-CIM mapping ([DSP0230](#)).

EXAMPLE: Example of VirtualHardwareSection:

```
<VirtualHardwareSection ovf:id="minimal" ovf:transport="iso">
  <Info>500Mb, 1 CPU, 1 disk, 1 nic virtual machine</Info>
  <System>
    <vssd:ElementName>Virtual System Type</vssd:ElementName>
    <vssd:InstanceID>0</vssd:InstanceID>
    <vssd:VirtualSystemType>vmx-4</vssd:VirtualSystemType>
  </System>
  <Item>
    <rasd:AllocationUnits>byte * 2^20</rasd:AllocationUnits>
    <rasd:Description>Memory Size</rasd:Description>
    <rasd:ElementName>512 MB of memory</rasd:ElementName>
    <rasd:InstanceID>2</rasd:InstanceID>
    <rasd:ResourceType>4</rasd:ResourceType>
    <rasd:VirtualQuantity>512</rasd:VirtualQuantity>
  </Item>
  <!-- Additional Item elements can follow -->
</VirtualHardwareSection>
```

A VirtualSystem element shall have a VirtualHardwareSection direct child element. VirtualHardwareSection is disallowed as a direct child element of a VirtualSystemCollection element and of an Envelope element.

Multiple VirtualHardwareSection element occurrences are allowed within a single VirtualSystem element. The consumer of the OVF package should select the most appropriate virtual hardware description for the particular virtualization platform. A VirtualHardwareSection element may contain an ovf:id attribute which can be used to identify the element. If present the attribute value must be unique within the VirtualSystem.

The `ovf:transport` attribute specifies the types of transport mechanisms by which properties are passed to the virtual machine in an OVF environment document. This attribute supports a pluggable and extensible architecture for providing guest/platform communication mechanisms. Several transport types may be specified separated by single space character. See 9.5 for a description of properties and clause 11 for a description of transport types and OVF environments.

The `vssd:VirtualSystemType` element specifies a virtual system type identifier, which is an implementation defined string that uniquely identifies the type of the virtual system. For example, a virtual system type identifier could be `vmx-4` for VMware's fourth-generation virtual hardware or `xen-3` for Xen's third-generation virtual hardware. Zero or more virtual system type identifiers may be specified, separated by single space character. In order for the OVF virtual system to be deployable on a target platform, the virtual machine on the target platform should support at least one of the virtual system types identified in the `vssd:VirtualSystemType` elements. The virtual system type identifiers specified in `vssd:VirtualSystemType` elements are expected to be matched against the values of property `VirtualSystemTypesSupported` of CIM class `CIM_VirtualSystemManagementCapabilities`.

The virtual hardware characteristics are described as a sequence of `Item` elements. The `Item` element is an XML representation of an instance of the CIM class `CIM_ResourceAllocationSettingData`. The element can describe all memory and CPU requirements as well as virtual hardware devices.

Multiple device subtypes may be specified in an `Item` element, separated by a single space character.

EXAMPLE:

```
<rasd:ResourceSubType>buslogic lsilogic</rasd:ResourceSubType>
```

8.2 Extensibility

The optional `ovf:required` attribute on the `Item` element specifies whether the realization of the element (for example, a CD-ROM or USB controller) is required for correct behavior of the guest software. If not specified, `ovf:required` defaults to `TRUE`.

On child elements of the `Item` element, the optional Boolean attribute `ovf:required` shall be interpreted, even though these elements are in a different RASD WS-CIM namespace. A tool parsing an `Item` element should act according to Table 2.

Table 2 – Actions for Child Elements with `ovf:required` Attribute

Child Element	<code>ovf:required</code> Attribute Value	Action
Known	<code>TRUE</code> or not specified	Shall interpret Item
Known	<code>FALSE</code>	Shall interpret Item
Unknown	<code>TRUE</code> or not specified	Shall fail Item
Unknown	<code>FALSE</code>	Shall ignore Item

8.3 Virtual Hardware Elements

The general form of any `Item` element in a `VirtualHardwareSection` element is as follows:

```
<Item ovf:required="..." ovf:configuration="..." ovf:bound="...">
  <rasd:Address> ... </rasd:Address>
  <rasd:AddressOnParent> ... </rasd:AddressOnParent>
  <rasd:AllocationUnits> ... </rasd:AllocationUnits>
  <rasd:AutomaticAllocation> ... </rasd:AutomaticAllocation>
  <rasd:AutomaticDeallocation> ... </rasd:AutomaticDeallocation>
```

```

<rasd:Caption> ... </rasd:Caption>
<rasd:Connection> ... </rasd:Connection>
<!-- multiple connection elements can be specified -->
<rasd:ConsumerVisibility> ... </rasd:ConsumerVisibility>
<rasd:Description> ... </rasd:Description>
<rasd:ElementName> ... </rasd:ElementName>
<rasd:HostResource> ... </rasd:HostResource>
<rasd:InstanceID> ... </rasd:InstanceID>
<rasd:Limit> ... </rasd:Limit>
<rasd:MappingBehavior> ... </rasd:MappingBehavior>
<rasd:OtherResourceType> ... </rasd:OtherResourceType>
<rasd:Parent> ... </rasd:Parent>
<rasd:PoolID> ... </rasd:PoolID>
<rasd:Reservation> ... </rasd:Reservation>
<rasd:ResourceSubType> ... </rasd:ResourceSubType>
<rasd:ResourceType> ... </rasd:ResourceType>
<rasd:VirtualQuantity> ... </rasd:VirtualQuantity>
<rasd:Weight> ... </rasd:Weight>
</Item>

```

The elements represent the properties exposed by the CIM_ResourceAllocationSettingData class. They have the semantics of defined settings as defined in [DSP1041](#), any profiles derived from [DSP1041](#) for specific resource types, and this document.

EXAMPLE: The following example shows a description of memory size:

```

<Item>
  <rasd:AllocationUnits>byte * 2^20</rasd:AllocationUnits>
  <rasd:Description>Memory Size</rasd:Description>
  <rasd:ElementName>256 MB of memory</rasd:ElementName>
  <rasd:InstanceID>2</rasd:InstanceID>
  <rasd:ResourceType>4</rasd:ResourceType>
  <rasd:VirtualQuantity>256</rasd:VirtualQuantity>
</Item>

```

The Description element is used to provide additional metadata about the element itself. This element enables a consumer of the OVF package to provide descriptive information about all items, including items that were unknown at the time the application was written.

The Caption, Description and ElementName elements are localizable using the ovf:msgid attribute from the OVF envelope namespace. See clause 10 for more details on internationalization support.

The optional ovf:configuration attribute contains a list of configuration names. See 9.8 on deployment options for semantics of this attribute. The optional ovf:bound attribute is used to specify ranges; see 8.4.

Devices such as disks, CD-ROMs, and networks need a backing from the deployment platform. The requirements on a backing are either specified using the HostResource or the Connection element.

For an Ethernet adapter, a logical network name is specified in the Connection element. Ethernet adapters that refer to the same logical network name within an OVF package shall be deployed on the same network.

The HostResource element is used to refer to resources included in the OVF descriptor as well as logical devices on the deployment platform. Values for HostResource elements referring to resources included in the OVF descriptor are formatted as URIs as specified in Table 3.

Table 3 – HostResource Element

Content	Description
ovf:/file/<id>	A reference to a file in the OVF, as specified in the References section. <id> shall be the value of the ovf:id attribute of the File element being referenced.
ovf:/disk/<id>	A reference to a virtual disk, as specified in the DiskSection. <id> shall be the value of the ovf:diskId attribute of the Disk element being referenced.

If no backing is specified for a device that requires a backing, the deployment platform shall make an appropriate choice, for example, by prompting the user. Specifying more than one backing for a device is not allowed.

Table 4 gives a brief overview on how elements are used to describe virtual devices and controllers.

Table 4 – Elements for Virtual Devices and Controllers

Element	Usage
rasd:Description	A human-readable description of the meaning of the information. For example, "Specifies the memory size of the virtual machine".
rasd:ElementName	A human-readable description of the content. For example, "256MB memory".
rasd:InstanceID	A unique instance ID of the element within the section.
rasd:HostResource	Abstractly specifies how a device shall connect to a resource on the deployment platform. Not all devices need a backing. See Table 3.
rasd:ResourceType rasd:OtherResourceType rasd:ResourceSubtype	Specifies the kind of device that is being described.
rasd:AutomaticAllocation	For devices that are connectable, such as floppies, CD-ROMs, and Ethernet adaptors, this element specifies whether the device should be connected at power on.
rasd:Parent	The InstanceID of the parent controller (if any).
rasd:Connection	For an Ethernet adapter, this specifies the abstract network connection name for the virtual machine. All Ethernet adapters that specify the same abstract network connection name within an OVF package shall be deployed on the same network. The abstract network connection name shall be listed in the NetworkSection at the outermost envelope level.
rasd:Address	Device specific. For an Ethernet adapter, this specifies the MAC address.
rasd:AddressOnParent	For a device, this specifies its location on the controller.
rasd:AllocationUnits	Specifies the units of allocation used. For example, "byte * 2 ²⁰ ".
rasd:VirtualQuantity	Specifies the quantity of resources presented. For example, "256".
rasd:Reservation	Specifies the minimum quantity of resources guaranteed to be available.
rasd:Limit	Specifies the maximum quantity of resources that are granted.
rasd:Weight	Specifies a relative priority for this allocation in relation to other allocations.

Only fields directly related to describing devices are mentioned. Refer to the [CIM MOF](#) for a complete description of all fields, each field corresponds to the identically named property in the CIM_ResourceAllocationSettingData class.

8.4 Ranges on Elements

The optional `ovf:bound` attribute may be used to specify ranges for the Item elements. A range has a minimum, normal, and maximum value, denoted by `min`, `normal`, and `max`, where `min <= normal <= max`. The default values for `min` and `max` are those specified for `normal`.

A platform deploying an OVF package is recommended to start with the normal value and adjust the value within the range for ongoing performance tuning and validation.

For the Item elements in VirtualHardwareSection and ResourceAllocationSection elements, the following additional semantics are defined:

- Each Item element has an optional `ovf:bound` attribute. This value may be specified as `min`, `max`, or `normal`. The value defaults to `normal`. If the attribute is not specified or is specified as `normal`, then the item is interpreted as being part of the regular virtual hardware or resource allocation description.

- If the `ovf:bound` value is specified as either `min` or `max`, the item is used to specify the upper or lower bound for one or more values for a given `InstanceID`. Such an item is called a range marker.

The semantics of range markers are as follows:

- `InstanceID` and `ResourceType` shall be specified, and the `ResourceType` shall match other `Item` elements with the same `InstanceID`.
- Specifying more than one `min` range marker or more than one `max` range marker for a given RASD (identified with `InstanceID`) is invalid.
- An `Item` element with a range marker shall have a corresponding `Item` element without a range marker, that is, an `Item` element with no `ovf:bound` attribute or `ovf:bound` attribute with value `normal`. This corresponding item specifies the default value.
- For an `Item` element where only a `min` range marker is specified, the `max` value is unbounded upwards within the set of valid values for the property.
- For an `Item` where only a `max` range marker is specified, the `min` value is unbounded downwards within the set of valid values for the property.
- The default value shall be inside the range.
- The use of non-integer elements in range marker RASDs is invalid.

EXAMPLE: The following example shows the use of range markers:

```
<VirtualHardwareSection>
  <Info>...</Info>
  <Item>
    <rasd:AllocationUnits>byte * 2^20</rasd:AllocationUnits>
    <rasd:ElementName>512 MB memory size</rasd:ElementName>
    <rasd:InstanceID>0</rasd:InstanceID>
    <rasd:ResourceType>4</rasd:ResourceType>
    <rasd:VirtualQuantity>512</rasd:VirtualQuantity>
  </Item>
  <Item ovf:bound="min">
    <rasd:AllocationUnits>byte * 2^20</rasd:AllocationUnits>
    <rasd:ElementName>384 MB minimum memory size</rasd:ElementName>
    <rasd:InstanceID>0</rasd:InstanceID>
    <rasd:Reservation>384</rasd:Reservation>
    <rasd:ResourceType>4</rasd:ResourceType>
  </Item>
  <Item ovf:bound="max">
    <rasd:AllocationUnits>byte * 2^20</rasd:AllocationUnits>
    <rasd:ElementName>1024 MB maximum memory size</rasd:ElementName>
    <rasd:InstanceID>0</rasd:InstanceID>
    <rasd:Reservation>1024</rasd:Reservation>
    <rasd:ResourceType>4</rasd:ResourceType>
  </Item>
</VirtualHardwareSection>
```

9 Core Metadata Sections

Table 5 shows the core metadata sections that are defined.

Table 5 – Core Metadata Sections

Section	Locations	Multiplicity
DiskSection Describes meta-information about all virtual disks in the package	Envelope	Zero or one
NetworkSection Describes logical networks used in the package	Envelope	Zero or one
ResourceAllocationSection Specifies reservations, limits, and shares on a given resource, such as memory or CPU for a virtual machine collection	VirtualSystemCollection	Zero or one
AnnotationSection Specifies a free-form annotation on an entity	VirtualSystem VirtualSystemCollection	Zero or one
ProductSection Specifies product-information for a package, such as product name and version, along with a set of properties that can be configured	VirtualSystem VirtualSystemCollection	Zero or more
EulaSection Specifies a license agreement for the software in the package	VirtualSystem VirtualSystemCollection	Zero or more
StartupSection Specifies how a virtual machine collection is powered on	VirtualSystemCollection	Zero or one
DeploymentOptionSection Specifies a discrete set of intended resource requirements	Envelope	Zero or one
OperatingSystemSection Specifies the installed guest operating system of a virtual machine	VirtualSystem	Zero or one
InstallSection Specifies that the virtual machine needs to be initially booted to install and configure the software	VirtualSystem	Zero or one

The following subclauses describe the semantics of the core sections and provide some examples. The sections are used in several places of an OVF envelope; the description of each section defines where it may be used. See the OVF schema for a detailed specification of all attributes and elements.

In the OVF schema, all sections are part of a substitution group with the Section element as head of the substitution group. The Section element is abstract and cannot be used directly.

9.1 DiskSection

A DiskSection describes meta-information about virtual disks in the OVF package. Virtual disks and their metadata are described outside the virtual hardware to facilitate sharing between virtual machines within an OVF package.

EXAMPLE: The following example shows a description of virtual disks:

```
<DiskSection>
  <Info>Describes the set of virtual disks</Info>
  <Disk ovf:diskId="vmdisk1" ovf:fileRef="file1" ovf:capacity="8589934592"
    ovf:populatedSize="3549324972"
    ovf:format=
      "http://www.vmware.com/interfaces/specifications/vmdk.html#sparse">
  </Disk>
  <Disk ovf:diskId="vmdisk2" ovf:capacity="536870912"
  </Disk>
  <Disk ovf:diskId="vmdisk3" ovf:capacity="${disk.size}"
    ovf:capacityAllocationUnits="byte * 2^30"
  </Disk>
</DiskSection>
```

DiskSection is a valid section at the outermost envelope level only.

Each virtual disk is represented by a Disk element that shall be given an identifier using the `ovf:diskId` attribute; the identifier shall be unique within the DiskSection.

The capacity of a virtual disk shall be specified by the `ovf:capacity` attribute with an `xs:long` integer value. The default unit of allocation shall be bytes. The optional string attribute `ovf:capacityAllocationUnits` may be used to specify a particular unit of allocation. Values for `ovf:capacityAllocationUnits` shall match the format for programmatic units defined in [DSP0004](#) with the restriction that the base unit shall be "byte".

The `ovf:fileRef` attribute denotes the virtual disk content by identifying an existing File element in the References element, the File element is identified by matching its `ovf:id` attribute value with the `ovf:fileRef` attribute value. Omitting the `ovf:fileRef` attribute shall indicate an empty disk. In this case, the disk shall be created and the entire disk content zeroed at installation time. The guest software will typically format empty disks in some file system format.

The format URI (see 5.2) of a non-empty virtual disk shall be specified by the `ovf:format` attribute.

Different Disk elements shall not contain `ovf:fileRef` attributes with identical values. Disk elements shall be ordered such that they identify any File elements in the same order as these are defined in the References element.

For empty disks, rather than specifying a fixed virtual disk capacity, the capacity for an empty disk may be given using an OVF property, for example `ovf:capacity="${disk.size}"`. The OVF property shall resolve to an `xs:long` integer value. See 9.5 for a description of OVF properties. The `ovf:capacityAllocationUnits` attribute is useful when using OVF properties because a user may be prompted and can then enter disk sizing information in ,for example, gigabytes.

For non-empty disks, the actual used size of the disk may optionally be specified using the `ovf:populatedSize` attribute. The unit of this attribute is always bytes. `ovf:populatedSize` is allowed to be an estimate of used disk size but shall not be larger than `ovf:capacity`.

In VirtualHardwareSection, virtual disk devices may have a `rasd:HostResource` element referring to a Disk element in DiskSection; see 8.3. The virtual disk capacity shall be defined by the `ovf:capacity` attribute on the Disk element. If a `rasd:VirtualQuantity` element is specified along with the `rasd:HostResource` element, the virtual quantity value shall not be considered and may have any value.

OVF allows a disk image to be represented as a set of modified blocks in comparison to a parent image. The use of parent disks can often significantly reduce the size of an OVF package, if it contains multiple disks with similar content. For a Disk element, a parent disk may optionally be specified using the `ovf:parentRef` attribute, which shall contain a valid `ovf:diskId` reference to a different Disk element. If a disk block does not exist locally, lookup for that disk block then occurs in the parent disk. In DiskSection, parent Disk elements shall occur before child Disk elements that refer to them.

9.2 NetworkSection

The NetworkSection element shall list all logical networks used in the OVF package.

```
<NetworkSection>
  <Info>List of logical networks used in the package</Info>
  <Network ovf:name="red">
    <Description>The network the Red service is available on</Description>
  </Network>
  <Network ovf:name="blue">
    <Description>The network the Blue service is available on</Description>
  </Network>
</NetworkSection>
```

NetworkSection is a valid element at the outermost envelope level.

All networks referred to from Connection elements in all VirtualHardwareSection elements shall be defined in the NetworkSection.

9.3 ResourceAllocationSection

The ResourceAllocationSection element describes all resource allocation requirements of a VirtualSystemCollection entity. These resource allocations shall be performed when deploying the OVF package.

```
<ResourceAllocationSection>
  <Info>Defines reservations for CPU and memory for the collection of VMs</Info>
  <Item>
    <rasd:AllocationUnits>byte * 2^20</rasd:AllocationUnits>
    <rasd:ElementName>300 MB reservation</rasd:ElementName>
    <rasd:InstanceID>0</rasd:InstanceID>
    <rasd:Reservation>300</rasd:Reservation>
    <rasd:ResourceType>4</rasd:ResourceType>
  </Item>
  <Item ovf:configuration="..." ovf:bound="...">
    <rasd:AllocationUnits>hertz * 10^6</rasd:AllocationUnits>
    <rasd:ElementName>500 MHz reservation</rasd:ElementName>
    <rasd:InstanceID>0</rasd:InstanceID>
    <rasd:Reservation>500</rasd:Reservation>
    <rasd:ResourceType>3</rasd:ResourceType>
  </Item>
</ResourceAllocationSection>
```

ResourceAllocationSection is a valid element for a VirtualSystemCollection entity.

The optional `ovf:configuration` attribute contains a list of configuration names. See 9.8 on deployment options for semantics of this attribute.

The optional `ovf:bound` attribute contains a value of `min`, `max`, or `normal`. See 8.4 for semantics of this attribute.

9.4 AnnotationSection

The `AnnotationSection` element is a user-defined annotation on an entity. Such annotations may be displayed when deploying the OVF package.

```
<AnnotationSection>
  <Info>An annotation on this service. It can be ignored</Info>
  <Annotation>Contact customer support if you have any problems</Annotation>
</AnnotationSection>
```

`AnnotationSection` is a valid element for a `VirtualSystem` and a `VirtualSystemCollection` entity.

See clause 10 for details on how to localize the `Annotation` element.

9.5 ProductSection

The `ProductSection` element specifies product-information for an appliance, such as product name, version, and vendor.

```
<ProductSection ovf:class="com.mycrm.myservice" ovf:instance="1">
  <Info>Describes product information for the service</Info>
  <Product>MyCRM Enterprise</Product>
  <Vendor>MyCRM Corporation</Vendor>
  <Version>4.5</Version>
  <FullVersion>4.5-b4523</FullVersion>
  <ProductUrl>http://www.mycrm.com/enterprise</ProductUrl>
  <VendorUrl>http://www.mycrm.com</VendorUrl>
  <Icon ovf:height="32" ovf:width="32" ovf:mimeType="image/png" ovf:fileRef="icon">
  <Category>Email properties</Category>
  <Property ovf:key="admin.email" ovf:type="string" ovf:userConfigurable="true">
    <Label>Admin email</Label>
    <Description>Email address of administrator</Description>
  </Property>
  <Category>Admin properties</Category>
  <Property ovf:key="app.log" ovf:type="string" ovf:value="low"
  ovf:userConfigurable="true">
    <Description>Loglevel for the service</Description>
  </Property>
  <Property ovf:key="app.isSecondary" ovf:value="false" ovf:type="boolean">
    <Description>Cluster setup for application server</Description>
  </Property>
  <Property ovf:key="app.ip" ovf:type="string" ovf:value="{appserver-vm}">
    <Description>IP address of the application server VM</Description>
  </Property>
</ProductSection>
```

The optional `Product` element specifies the name of the product, while the optional `Vendor` element specifies the name of the product vendor. The optional `Version` element specifies the product version in short form, while the optional `FullVersion` element describes the product version in long form. The optional `ProductUrl` element specifies a URL which shall resolve to a human readable description of the product, while the optional `VendorUrl` specifies a URL which shall resolve to a human readable description of the vendor.

The optional `AppUrl` element specifies a URL resolving to the deployed product instance; this element is experimental. The optional `Icon` element specifies display icons for the product; this element is experimental.

Property elements specify application-level customization parameters and are particularly relevant to appliances that need to be customized during deployment with specific settings such as network identity, the IP addresses of DNS servers, gateways, and others.

`ProductSection` is a valid section for a `VirtualSystem` and a `VirtualSystemCollection` entity.

Property elements may be grouped by using `Category` elements. The set of `Property` elements grouped by a `Category` element is the sequence of `Property` elements following the `Category` element, until but not including an element that is not a `Property` element. For OVF packages containing a large number of `Property` elements, this may provide a simpler installation experience. Similarly, each `Property` element may have a short label defined by its `Label` child element in addition to a description defined by its `Description` child element. See clause 10 for details on how to localize the `Category` element and the `Description` and `Label` child elements of the `Property` element.

Each `Property` element in a `ProductSection` shall be given an identifier that is unique within the `ProductSection` using the `ovf:key` attribute.

Each `Property` element in a `ProductSection` shall be given a type using the `ovf:type` attribute and optionally type qualifiers using the `ovf:qualifiers` attribute. Valid types are listed in Table 6, and valid qualifiers are listed in Table 7.

The optional attribute `ovf:value` is used to provide a default value for a property. One or more optional `Value` elements may be used to define alternative default values for specific configurations, as defined in 9.8.

The optional attribute `ovf:userConfigurable` determines whether the property value is configurable during the installation phase. If `ovf:userConfigurable` is `FALSE` or omitted, the `ovf:value` attribute specifies the value to be used for that customization parameter during installation. If `ovf:userConfigurable` is `TRUE`, the `ovf:value` attribute specifies a default value for that customization parameter, which may be changed during installation.

A simple OVF implementation such as a command-line installer typically uses default values for properties and does not prompt even though `ovf:userConfigurable` is set to `TRUE`. To force prompting at startup time, omitting the `ovf:value` attribute is sufficient for integer types, because the empty string is not a valid integer value. For string types, prompting may be forced by adding a qualifier requiring a non-empty string, see Table 7.

The optional Boolean attribute `ovf:password` indicates that the property value may contain sensitive information. The default value is `FALSE`. OVF implementations prompting for property values are advised to obscure these values when `ovf:password` is set to `TRUE`. This is similar to HTML text input of type `password`. Note that this mechanism affords limited security protection only. Although sensitive values are masked from casual observers, default values in the OVF descriptor and assigned values in the OVF environment are still passed in clear text.

Zero or more ProductSections may be specified within a VirtualSystem or VirtualSystemCollection. Typically, a ProductSection corresponds to a particular software product that is installed. Each product section at the same entity level shall have a unique ovf: class and ovf: instance attribute pair. For the common case where only a single ProductSection is used, the ovf: class and ovf: instance attributes are optional and default to the empty string. It is recommended that the ovf: class property be used to uniquely identify the software product using the reverse domain name convention. Examples of values are com.vmware.tools and org.apache.tomcat. If multiple instances of the same product are installed, the ovf: instance attribute is used to identify the different instances.

Property elements are exposed to the guest software through the OVF environment, as described in clause 11. The value of the ovf: env: key attribute of a Property element exposed in the OVF environment shall be constructed from the value of the ovf: key attribute of the corresponding Property element defined in a ProductSection entity of an OVF descriptor as follows:

```
key-value-env = [class-value "."] key-value-prod [ "." instance-value]
```

where:

- class-value is the value of the ovf: class attribute of the Property element defined in the ProductSection entity. The production [class-value "."] shall be present if and only if class-value is not the empty string.
- key-value-prod is the value of the ovf: key attribute of the Property element defined in the ProductSection entity.
- instance-value is the value of the ovf: instance attribute of the Property element defined in the ProductSection entity. The production ["." instance-value] shall be present if and only if instance-value is not the empty string.

EXAMPLE: The following OVF environment example shows how properties can be propagated to the guest software:

```
<Property ovf:key="com.vmware.tools.logLevel" ovf:value="none"/>
<Property ovf:key="org.apache.tomcat.logLevel.1" ovf:value="debug"/>
<Property ovf:key="org.apache.tomcat.logLevel.2" ovf:value="normal"/>
```

The consumer of an OVF package should prompt for properties where ovf: userConfigurable is TRUE. These properties may be defined in multiple ProductSections as well as in sub-entities in the OVF package.

If a ProductSection exists, then the first ProductSection entity defined in the top-level Content element of a package shall define summary information that describes the entire package. After installation, a consumer of the OVF package could choose to make this information available as an instance of the CIM_Product class.

Property elements specified on a VirtualSystemCollection are also seen by its immediate children (see clause 11). Children may refer to the properties of a parent VirtualSystemCollection using macros on the form \${name} as value for ovf: value attributes.

Table 6 lists the valid types for properties. These are a subset of CIM intrinsic types defined in [DSP0004](#), which also define the value space and format for each intrinsic type. Each Property element shall specify a type using the ovf: type attribute.

Table 6 – Property Types

Type	Description
uint8	Unsigned 8-bit integer
sint8	Signed 8-bit integer
uint16	Unsigned 16-bit integer
sint16	Signed 16-bit integer
uint32	Unsigned 32-bit integer
sint32	Signed 32-bit integer
uint64	Unsigned 64-bit integer
sint64	Signed 64-bit integer
string	String
boolean	Boolean
real32	IEEE 4-byte floating point
real64	IEEE 8-byte floating point

Table 7 lists the supported CIM type qualifiers as defined in [DSP0004](#). Each Property element may optionally specify type qualifiers using the `ovf:qualifiers` attribute with multiple qualifiers separated by commas; see production `qualifierList` in ANNEX A “MOF Syntax Grammar Description” in [DSP0004](#).

Table 7 – Property Qualifiers

Type	Description
string	MinLen(min) MaxLen(max) ValueMap{...}
uint8	ValueMap{...}
sint8	
uint16	
sint16	
uint32	
sint32	
uint64	
sint64	

9.6 EulaSection

A `EulaSection` contains the legal terms for using its parent Content element. This license shall be shown and accepted during deployment of an OVF package. Multiple `EulaSections` may be present in an OVF. If unattended installations are allowed, all embedded license sections are implicitly accepted.

```
<EulaSection>
  <Info>Licensing agreement</Info>
  <License>
    Lorem ipsum dolor sit amet, ligula suspendisse nulla pretium, rhoncus tempor placerat
    fermentum, enim integer ad vestibulum volutpat. Nisl rhoncus turpis est, vel elit,
    congue wisi enim nunc ultricies sit, magna tincidunt. Maecenas aliquam maecenas ligula
```

```
nostra, accumsan taciti. Sociis mauris in integer, a dolor netus non dui aliquet,
sagittis felis sodales, dolor sociis mauris, vel eu libero cras. Interdum at. Eget
habitasse elementum est, ipsum purus pede porttitor class, ut adipiscing, aliquet sed
auctor, imperdiet arcu per diam dapibus libero duis. Enim eros in vel, volutpat nec
pellentesque leo, scelerisque.
```

```
</License>
</EulaSection>
```

EulaSection is a valid section for a VirtualSystem and a VirtualSystemCollection entity.

See clause 10 for details on how to localize the License element.

9.7 StartupSection

The StartupSection specifies how a virtual machine collection is powered on and off.

```
<StartupSection>
  <Item ovf:id="vm1" ovf:order="0" ovf:startDelay="30" ovf:stopDelay="0"
    ovf:startAction="powerOn" ovf:waitingForGuest="true"
    ovf:stopAction="powerOff"/>
  <Item ovf:id="teamA" ovf:order="0"/>
  <Item ovf:id="vm2" ovf:order="1" ovf:startDelay="0" ovf:stopDelay="20"
    ovf:startAction="powerOn" ovf:stopAction="guestShutdown"/>
</StartupSection>
```

Each Content element that is a direct child of a VirtualSystemCollection may have a corresponding Item element in the StartupSection entity of the VirtualSystemCollection entity. Note that Item elements may correspond to both VirtualSystem and VirtualSystemCollection entities. When a start or stop action is performed on a VirtualSystemCollection entity, the respective actions on the Item elements of its StartupSection entity are invoked in the specified order. Whenever an Item element corresponds to a (nested) VirtualSystemCollection entity, the actions on the Item elements of its StartupSection entity shall be invoked before the action on the Item element corresponding to that VirtualSystemCollection entity is invoked (i.e., depth-first traversal).

The following required attributes on Item are supported for a VirtualSystem and VirtualSystemCollection:

- `ovf:id` shall match the value of the `ovf:id` attribute of a Content element which is a direct child of this VirtualSystemCollection. That Content element describes the virtual machine or virtual machine collection to which the actions defined in the Item element apply.
- `ovf:order` specifies the startup order using non-negative integer values. The order of execution of the start action is the numerical ascending order of the values. Items with same order identifier may be started up concurrently. The order of execution of the stop action is the numerical descending order of the values.

The following optional attributes on Item are supported for a VirtualSystem.

- `ovf:startDelay` specifies a delay in seconds to wait until proceeding to the next order in the start sequence. The default value is 0.
- `ovf:waitingForGuest` enables the platform to resume the startup sequence after the guest software has reported it is ready. The interpretation of this is deployment platform specific. The default value is FALSE.
- `ovf:startAction` specifies the start action to use. Valid values are `powerOn` and `none`. The default value is `powerOn`.

- `ovf:stopDelay` specifies a delay in seconds to wait until proceeding to the previous order in the stop sequence. The default value is 0.
- `ovf:stopAction` specifies the stop action to use. Valid values are `powerOff`, `guestShutdown`, and `none`. The interpretation of `guestShutdown` is deployment platform specific. The default value is `powerOff`.

If not specified, an implicit default `Item` is created for each entity in the collection with `ovf:order="0"`. Thus, for a trivial startup sequence no `StartupSection` needs to be specified.

9.8 DeploymentOptionSection

The `DeploymentOptionSection` specifies a discrete set of intended resource configurations. The author of an OVF package can include sizing metadata for different configurations. A consumer of the OVF shall select a configuration, for example, by prompting the user. The selected configuration is visible in the OVF environment, enabling guest software to adapt to the selected configuration. See clause 11.

The `DeploymentOptionSection` specifies an ID, label, and description for each configuration.

```
<DeploymentOptionSection>
  <Configuration ovf:id="Minimal">
    <Label>Minimal</Label>
    <Description>Some description</Description>
  </Configuration>
  <Configuration ovf:id="Typical" ovf:default="true">
    <Label>Typical</Label>
    <Description>Some description</Description>
  </Configuration>
  <!-- Additional configurations -->
</DeploymentOptionSection>
```

The `DeploymentOptionSection` has the following semantics:

- If present, the `DeploymentOptionSection` is valid only at the envelope level, and only one section shall be specified in an OVF descriptor.
- The discrete set of configurations is described with `Configuration` elements, which shall have identifiers specified by the `ovf:id` attribute that are unique in the package.
- A default `Configuration` element may be specified with the optional `ovf:default` attribute. If no default is specified, the first element in the list is the default. Specifying more than one element as the default is invalid.
- The `Label` and `Description` elements are localizable using the `ovf:msgid` attribute. See clause 10 for more details on internationalization support.

Configurations may be used to control resources for virtual hardware and for virtual machine collections. `Item` elements in `VirtualHardwareSection` elements describe resources for `VirtualSystem` entities, while `Item` elements in `ResourceAllocationSection` elements describe resources for virtual machine collections. For these two `Item` types, the following additional semantics are defined:

- Each `Item` has an optional `ovf:configuration` attribute, containing a list of configurations separated by a single space character. If not specified, the item shall be selected for any configuration. If specified, the item shall be selected only if the chosen configuration ID is in the list. A configuration attribute shall not contain an ID that is not specified in the `DeploymentOptionSection`.
